Organisation profile

Education
We offer a range of courses and programmes within manufacturing, product design, production tech-nology, strategy, econo-mics, management, orga-nisation, sociotechnical design, entrepreneurship and sustainability.

Research
Our main research areas are innovation, product development, production management, sustain-ability, construction mana-gement and operations research.

Industrial collaboration
We emphasise the transfer of knowledge between industry and academia. Research co-operation can take many forms: industrial PhD projects; research consortiums; innovation contracts, and collaboration agreements.

Publications:

ASTA - A method for multi-criteria evaluation of water supply technologies to Assess the most SusTainable Alternative for Copenhagen
Utilities in larger cities have to make complex decisions planning future investments in urban water infrastructure. Changes are driven by physical water stress or political targets for environmental water flows e.g. through the implementation of the European water framework directive. To include these environmental, economic and social sustainability dimensions we introduce a novel multi-criteria assessment method for evaluation of water supply technologies. The method is presented and demonstrated for four alternatives for water supply based on groundwater, rain- & stormwater or seawater developed for augmenting Copenhagen's current groundwater based water supply. To identify the most sustainable technology, we applied rank order distribution weights to a multi-criteria decision analysis to combine the impact assessments of environment, economy and society. The three dimensions were assessed using 1) life-cycle assessment, 2) cost calculations taking operation and maintenance into account and 3) the multi-criteria decision analysis method Analytical hierarchy process. Specialists conducted the life-cycle assessment and cost calculations and the multi-criteria decision analyses were based on a stakeholder workshop gathering stakeholders relevant for the specific case. The workshop reached consensus on three sets of ranked criteria. Each set represented stakeholder perspectives with first priority given to one of the three sustainability dimensions or categories. The workshop reached consensus and when the highest weight was assigned to the environmental dimension of sustainability then the alternative of 'Rain- & stormwater harvesting' was the most sustainable water supply technology; when the highest weight was assigned to the economy or society dimensions then an alternative with 'Groundwater abstraction extended with compensating actions' was considered the most sustainable water supply technology. Across all three sets of ranked weights, the establishment of new well fields is considered the least sustainable alternative.
Biodiversity of soil bacteria exposed to sub-lethal concentrations of phosphonium-based ionic liquids: Effects of toxicity and biodegradation

Little is known about the effect of ionic liquids (ILs) on the structure of soil microbial communities and resulting biodiversity. Therefore, we studied the influence of six trihexyl(tetradecyl)phosphonium ILs (with either bromide or various organic anions) at sublethal concentrations on the structure of microbial community present in an urban park soil in 100-day microcosm experiments. The biodiversity decreased in all samples (Shannon's index decreased from 1.75 down to 0.74 and OTU’s number decreased from 1399 down to 965) with the largest decrease observed in the microcosms spiked with ILs where biodegradation extent was higher than 80%. (i.e. [P66614][Br] and [P66614][2,4,4]). Despite this general decrease in biodiversity, which can be explained by ecotoxic effect of the ILs, the microbial community in the microcosms was enriched with Gram-negative hydrocarbon-degrading genera e.g. Sphingomonas. It is hypothesized that, in addition to toxicity, the observed decrease in biodiversity and change in the microbial community structure may be explained by the primary biodegradation of the ILs or their metabolites by the mentioned genera, which outcompeted other microorganisms unable to degrade ILs or their metabolites. Thus, the introduction of phosphonium-based ILs into soils at sub-lethal concentrations may result not only in a decrease in biodiversity due to toxic effects, but also in enrichment with ILs-degrading bacteria.

Can farmers mitigate environmental impacts through combined production of food, fuel and feed? A consequential life cycle assessment of integrated mixed crop-livestock system with a green biorefinery

This study evaluates environmental impacts of an integrated mixed crop-livestock system with a green biorefinery (GBR). System integration included production of feed crops and green biomasses (Sys-I) to meet the demand of a livestock system (Sys-III) and to process green biomasses in a GBR system (Sys-II). Processing of grass-clover to produce feed protein was considered in Sys-II, particularly to substitute the imported soybean meal. Waste generated from the livestock and GBR systems were considered for the conversion to biomethane (Sys-IV). Digestate produced therefrom was assumed to be recirculated back to the farmers' field (Sys-I). A consequential approach of Life Cycle Assessment (LCA) method was used to evaluate the environmental impacts of a combined production of suckler cow calves (SCC) and Pigs, calculated in terms of their live weight (LW). The functional unit (FU) was a basket of two products “1kgLW-SCC+1kgLW-Pigs”, produced at the farm gate. Results obtained per FU were: 19.6kg CO2 eq for carbon footprint; 0.11kg PO4 eq for eutrophication potential, -129MJ eq for non-renewable energy use and -3.9 comparative toxicity units (CTUe) for potential freshwater ecotoxicity. Environmental impact, e.g. greenhouse gas (GHG) emission was primarily due to (i) N2O emission and diesel consumption within Sys-I, (ii) energy input to Sys-II, III and IV, and (iii) methane emission from Sys-III and Sys-IV. Specifically, integrating GBR with the mixed crop-livestock system contributed 4% of the GHG emissions, whilst its products credited 7% of the total impact. Synergies among the different sub-systems showed positive environmental gains for the selected main products. The main effects of the system integration were in the reductions of GHG emissions, fossil fuel consumption, eutrophication potential and freshwater ecotoxicity, compared to a conventional mixed crop-livestock system, without the biogas conversion facility and the GBR.
Considering built environment and spatial correlation in modelling pedestrian injury severity

This study looks at mitigating and aggravating factors that are associated with the injury severity of pedestrians when they have crashes with another road user and overcomes existing limitations in the literature by posing attention on the built environment and considering spatial correlation across crashes. Reports for 6539 pedestrian crashes occurred in Denmark between 2006 and 2015 were merged with geographic information system resources containing detailed information about built environment and exposure at the crash locations. A linearised spatial logit model estimated the probability of pedestrians to sustain a severe or fatal injury conditional on the occurrence of a crash with another road user. This study confirms previous findings about older pedestrians and intoxicated pedestrians being the most vulnerable road users, and crashes with heavy vehicles and in roads with higher speed limits being related to the most severe outcomes. This study provides also novel perspectives by showing positive spatial correlation of crashes with the same severity outcome and emphasising the role of the built environment in the proximity of the crash. This study emphasises the need for thinking about traffic calming measures, illumination solutions, road maintenance programs and speed limit reductions. Moreover, this study emphasises the role of the built environment, as shopping areas, residential areas, and walking traffic density are positively related to a reduction in pedestrian injury severity. Often, these areas have in common a larger pedestrian mass that is more likely to make other road users more aware and attentive, while the same does not seem to apply to areas with lower pedestrian density.

Decarbonising the Finnish Transport Sector by 2050: Electricity or Biofuels?

Finland has set ambitious long-term targets, which aim to reduce greenhouse gas emissions from the transport sector and the whole energy system by 2050. By utilising the energy system model STREAM, which includes the power, heat and transport sectors, this paper develops two alternative scenarios for the transport sector by 2050—one with a high percentage of electric vehicles (EV) and another with a high percentage of biofuels (BIO), and compares the scenario results with a known Carbon-Neutral Scenario (CNS) which is adopted from the Nordic Energy Technology Perspective (IEA in Nordic energy technology perspective—pathways to a carbon-neutral energy future, 2013a). The socio-economic value of the total system cost is computed and the system integration of the transport sector with the electricity and heating sectors is simulated with an hourly time resolution. This study finds that a Finnish transport sector with a high share of EV by 2050 leads to the lowest total annual system cost of the scenarios and yields a reduction by 2.3% compared to CNS. While the transport configuration in the BIO scenario achieves the highest total annual system cost which is 0.4% higher than CNS. The robustness of the results is tested through a sensitivity analysis which shows that the costs (investment and maintenance) of biodiesel cars and EV are the most sensitive parameters in the comparative analysis of the scenarios.

Editorial: Operational Research – Making an Impact
The origins of Operational Research are well known. OR developed – in particular in the UK - in the early 1940s as an area in which science was applied and new research inspired by real-world challenges, primarily in military analysis and in industrial production. As OR developed, a community of academic OR scholars became established alongside OR practitioners and this has led quite naturally to the situation that, over time, much of the OR academic literature is inspired by theoretical development rather than by immediate application.

Effects of new bus and rail rapid transit systems – an international review

Cities worldwide are implementing modern transit systems to improve mobility in the increasingly congested metropolitan areas. Despite much research on the effects of such systems, a comparison of effects across transit modes and countries has not been studied comprehensively. This paper fills this gap in the literature by reviewing and comparing the effects obtained by 86 transit systems around the world, including Bus Rapid Transit (BRT), Light Rail Transit (LRT), metro and heavy rail transit systems. The analysis is twofold by analysing (i) the direct operational effects related to travel time, ridership and modal shifts, and (ii) the indirect strategic effects in terms of effects on property values and urban development. The review confirms the existing literature suggesting that BRT can attract many passengers if travel time reductions are significantly high. This leads to attractive areas surrounding the transit line with increasing property values. Such effects are traditionally associated with attractive rail-based public transport systems. However, a statistical comparison of 41 systems did not show significant deviations between effects on property values resulting from BRT, LRT and metro systems, respectively. Hence, this paper indicates that large strategic effects can be obtained by implementing BRT systems at a much lower cost.
Electric bus fleet size and mix problem with optimization of charging infrastructure

Battery electric buses are seen as a well-suited technology for the electrification of road-based public transport. However, the transition process from conventional diesel to electric buses faces major hurdles caused by range limitations and required charging times of battery buses. This work addresses these constraints and provides a methodology for the cost-optimized planning of depot charging battery bus fleets and their corresponding charging infrastructure. The defined problem covers the scheduling of battery buses, the fleet composition, and the optimization of charging infrastructure in a joint process. Vehicle schedule adjustments are monetized and evaluated together with the investment and operational costs of the bus system. The resulting total cost of ownership enables a comparison of technical alternatives on a system level, which makes this approach especially promising for feasibility studies comprising a wide range of technical concepts. Two scenarios of European cities are analyzed and discussed in a case study, revealing that the cost structure is influenced significantly by the considered bus type and its technical specifications. For example, the total energy consumption of the considered lightweight bus is up to 32% lower than the total consumption of the high range bus, although the deadheading mileage increases. However, the total costs of ownership for operating both bus types are relatively close, due to the increased fleet size and driver expenses required for the lightweight bus system. The case study furthermore reveals that a mixed fleet of different bus types could be advantageous depending on the operational characteristics of the bus route.

Introduction to Part III: Application of LCA in Practice
While Part II of this book presents the theoretical foundation and methodology of LCA, Part III is dedicated to a comprehensive discussion of how this methodology has been adapted and applied in practice. The chapters of Part III provide an easily readable and accessible introduction to different fields of LCA application with their specific decision situations, user competences and stakeholder needs, and associated methodological challenges and adaptations.

LCA of Electromobility
Private transportation is increasingly responsible for a significant share of GHG emissions. In this context, electric vehicles (EVs) are considered to be a key technology to reduce the environmental impact caused by the mobility sector. While EVs do offer an opportunity to decrease the production of greenhouse gases radically by avoiding the generation of tailpipe emissions, different technological challenges must be overcome. On the one side, the production of the battery system is of significant importance as it is reckoned to be responsible for around 40–50% of the total CO2-eq. emissions of the vehicle’s manufacturing stage. Moreover, the additional requirements for metals like copper and aluminium for the battery system as well as rare earth metals for the production of electric motors might lead to shifting the problem to other life cycle stages or areas of impact. On the other side, the source of the energy used to power an EV has an ultimate influence on the environmental impact caused during the vehicle’s use stage. The life cycle assessment methodology is normally used to measure the environmental impact of electric vehicles and to identify potential problem shifting. In this chapter, we present an overview of the application of the methodology within the electric mobility sector.

LCA of Wastewater Treatment
The main purpose of wastewater treatment is to protect humans against waterborne diseases and to safeguard aquatic bio-resources like fish. The dominating environmental concerns within this domain are indeed still potential aquatic eutrophication/oxygen depletion due to nutrient/organic matter emissions and potential health impacts due to spreading of pathogens. Anyway, the use of treatment for micro-pollutants is increasing and a paradigm shift is ongoing — wastewater is more and more considered as a resource of, e.g. energy, nutrients and even polymers, in the innovations going on. The
focus of LCA studies addressing wastewater treatment have from the very first published cases, been on energy and resource consumption. In recent time, the use of characterisation has increased and besides global warming potential, especially eutrophication is in focus. Even the toxicity-related impact categories are nowadays included more often. Application of LCA for comparing avoided against induced impacts, and hereby identifying trade-offs when introducing new technology, is increasingly used. A typical functional unit is the treatment of one cubic metre of wastewater which should be well defined regarding composition. Depending on the goal and scope of the study, all life cycle stages have the potential of being significant, though disposal of infrastructure seems to be the least important for the impact profile in many cases. No inventory data and none of the conventional impact categories (except stratospheric ozone depletion if emission of N2O is excluded) should be ruled out; but eutrophication and ecotoxicity are in many cases among the dominating ones.

Life Cycle Costing: An Introduction
The chapter gives an introduction to life cycle costing (LCC) and how it can be used to support decision-making. It can form the economic pillar in a full life cycle sustainability assessment, but often system delimitations differ depending on the goal and scope of the study. To provide a profound understanding this chapter describes several approaches and terms, fundamental principles and different types of costs. A brief introduction is given to conventional LCC and societal LCC but the main focus is on environmental Life Cycle Costing (eLCC) as the LCC approach that is compatible with environmental Life Cycle Assessment (LCA) in terms of system delimitation. Differences are explained and addressed, and an overview is given of the main cost categories to consider from different user perspectives. As inventory data is often sensitive in financial analyses, a list of relevant databases is provided as well as guidance on how to collect data to overcome this hurdle. In an illustrative case study on window frames, the eLCC theory is applied and demonstrated with each step along the eLCC procedure described in detail. A final section about advanced LCC introduces how to monetarise externalities and how to do discounting.

Life Cycle Thinking and the Use of LCA in Policies Around the World
The chapter explains what Sustainable Consumption and Production (SCP) is about, why it is about taking a life cycle approach and shows that SCP-related policies have been developed at the intergovernmental level and in different
regions of the world. A key element at the international level is the 10-Year Framework of Programmes on SCP adopted in 2012 and the global agreements on the Sustainable Development Goals (SDGs) adopted in 2015. Life cycle thinking has become mature, moving from its academic origins and limited uses, primarily in-house in large companies, to more powerful approaches that can support the provision of more sustainable goods and services through efficient use in product development, external communications, in support of customer choice, and in public debates. Now governments can use LCA for SCP policies. For this purpose LCA databases are needed. LCA is in particular relevant for policies focusing on design for sustainability, sustainable consumer information, sustainable procurement and waste management, minimization and prevention as well as sector-specific policies like sustainable energy and food supply. Examples of life cycle thinking and the use of LCA in policies are provided for numerous countries around the world but with a certain focus on the European Union. It can be expected that the use of LCA in policies for the sustainability assessment of products will further increase, also slowly covering more means of implementation such as incentives and legislative obligations.

Organisational LCA
The most applied and widespread approaches for environmental assessments at the organisation level have only recently extended their view beyond the factory gates. Even if they now consider the full value chain, they still mostly concentrate on a single environmental aspect like greenhouse gases (GHGs). While LCA was originally developed for products, its benefits and potential can be extended to the assessment of organisations. Organisational LCA is built on the principles, requirements and guidelines of ISO 14040 and ISO 14044, but requires some adaptations in the scope and inventory phases, when the unit of analysis and the system boundaries are defined. Also, the approach for data collection needs to be fixed. Organisational LCA is a compilation and evaluation of the inputs, outputs and potential environmental impacts of the activities associated with the organisation adopting a life cycle perspective. It includes not only the facilities of the organisation itself, but also the activities upstream and downstream the value chain. This methodology is capable of serving multiple goals at the same time, like identifying environmental hotspots throughout the value chain, tracking environmental performance over time, supporting strategic decisions, and informing corporate sustainability reporting. Several initiatives are on the way for the LCA of organisations: the UNEP/SETAC Life Cycle Initiative published the ‘Guidance on organizational LCA’, using ISO/TS 14072 as a backbone; moreover, the European Commission launched a guide for the organisation environmental footprint.

Overview of Existing LCIA Methods—Annex to Chapter 10
The chapter gives an overview and a systematic comparison of a selection of the most used Life Cycle Impact
Assessment (LCIA) methods, focusing on methods that have been implemented and made available in LCA software.
Currently available midpoint and endpoint characterisation methodologies are presented and their specific properties are
qualitatively compared in detailed tables.

Project studies: What it is, where it is going
Project organising is a growing field of scholarly inquiry and management practice. In recent years, two important
developments have influenced this field: (1) the study and practice of projects have extended their level of analysis from
mainly focussing on individual projects to focussing on micro- as well as macro-level concerns around projects; and (2)
there has been a greater interest in different kinds of scholarly inquiry. Taken together, these two developments call for
closer scrutiny of how the levels of analysis and the types of inquiry are related and benefit each other, and of the
explanations of project practices they could offer. To discuss avenues for future research on projects and project practice,
this paper suggests the notion of project studies to better grasp the status of our field. We combine these two sets of ideas
to analyse the status and future options for advancing project research: (1) levels of analysis; and (2) type of research.
Analysing recent developments within project studies, we observe the emergence of what we refer to as type 3 research,
which reconciles the need for theoretical development and engagement with practice. Type 3 research suggests
pragmatic avenues to move away from accepted yet unhelpful assumptions about projects and project organising.
The paper ends with an agenda for future research on projects and project practice, which offers project scholars a variety of options to position themselves in
the field of project studies, and to explore opportunities in the crossroads between levels of analysis and types of
research. Executive summary: Rapid diversification of scholarly inquiry and management practice in projects may
segregate the project research, but could also constitute an opportunity to strengthening it. For example, the diversity of
‘organisations’ or forms of ‘organising’ filled the field of organisation studies with new ideas and intellectual challenges. To
take advantage of such developments, organisational scholars had to consider different forms of organising as part of
‘organisation studies’, and continuously adapt their frames of reference and forms of conceptualisations organisations as a
‘research field’ and a ‘research object’. Concomitantly, they embraced alternative research interests, ontologies and
epistemologies, which today enrich the field. Such dynamics build on scholarly reflexivity and could also, we believe, be
fostered in project research. Thus, responding to the diversification of the field, and inspired by the notion of ‘organisation
studies’, we present the case of ‘project studies’, which acts as an umbrella for the studies in, on and around projects.
‘Project studies’ is novel as it does not propose an alternative perspective on projects, but instead calls for an inclusive
and integrative research field for all perspectives, fostering vibrant dialogue and debate that welcomes different opinions
and perspectives. The aim of the present paper is to demonstrate the value of the notion of project studies and to call for
reflexive scholars capable of navigating diversity by positioning their research in contrast with that of others. In particular,
we focus on two recent developments that have contributed to the diversification of the field and offered new options for
project scholars: (1) the study and practice of projects have extended their level of analysis from mainly focussing on
individual projects to focussing on micro- as well as macro-level concerns around projects; and. (2) there has been a
greater interest in different kinds of scholarly inquiry. We examined the different types of inquiries through the lenses of the
three deep-seeded human interests proposed by Habermas: a) The traditional positivist tradition has its main interest on
‘solving the problems’ of project organising and increase its efficiency and effectiveness through better understanding of
causal relationships surrounding projects. b) Interpretative research is grounded on our inherent interest to understand the
world around us, but not necessarily ‘solve’ it. Rather, this research explores perceptions, behaviours and sees the world
not so much in terms of causal-links, but complex networks with interesting cases and possibilities for learning. c) 
Emancipatory research is driven by emancipatory interest and the pragmatic desire for changes in the status quo through 
the reorganisation of inherent contradictions, giving voice to minorities while addressing major economic and social 
problems. We termed them type 1, type 2 and type 3, respectively. The juxtaposition of levels of analysis and types of 
research offers a matrix with nine areas to identify opportunities and to position research contributions a in the field of 
project studies, extending current treatments of problems and topics to different levels of analysis and types of research. 
In particular, we would also welcome the strengthening of type 3 research across the three primary levels of analysis 
addressed in the present paper. This paper provides a framework to encourage project scholars to reflect and become 
even more aware of nature and conduct of their research: the kinds of knowledge and interests they pursue, as well as the 
focus of their research. Our framework and analysis are exploratory and only build a tentative foundation for further 
exploration. We hope the present paper will trigger reflexivity on the making of project studies. In this spirit, we welcome 
further development as well as criticism to our main ideas.

Supply chain collaboration in industrial symbiosis networks

A strategy supporting the development towards a circular economy is industrial symbiosis (IS). It is a form of collaborative supply chain management aiming to make industry more sustainable and achieve collective benefits based on utilization of waste, by-products, and excess utilities between economically independent industries. Based on an extensive analysis of published studies on existing IS collaborations and interviews with central stakeholders of a comprehensive IS, this paper investigates IS from a supply chain collaboration perspective. A theoretical framework is built and used to discuss how industrial symbiosis pursues sustainability and to identify the main collaboration aspects and performance impacts. This framework is then used in the analysis of selected published cases. Based on this, we derive propositions on the organizational and operational requirements for collaboration in the context of IS networks, related to the supply chain integration and coordination practices. As IS has only received little attention in the operations and supply chain management community, our propositions directly lead to future research directions. Furthermore, the analysis in this paper provides directions to increase the feasibility and resource efficiency of IS networks and can hence be used by stakeholders involved in these networks.
The evolution of facility management business models in supplier–client relationships

Purpose – The study improves the current understanding of business model innovation by outlining how business models unfold over time within supplier–client relationships in facilities management (FM) services.

Design/methodology/approach – This study of FM services in Denmark consists of an explorative case study and three case studies of facilities management clients. Both phases, related and overlapping, involved collection and analysis of in-depth, semi-structured interviews and archive data.

Findings – Findings shows that business model innovation entails interorganisational collaboration across different phases of the innovation process. The research demonstrates that external orientation within FM service ecosystems involves both a reaction to changes in the external environment and the proactive involvement of stakeholders throughout business model innovation.

Research limitations/implications – The selection of business model innovation processes was limited to the Danish context. The sample, although heterogeneous and representative, represented only a fraction of the total population, which may have excluded processes of business model innovation that contradict the research.

Practical implications – This paper suggests that by observing the business models of the value network over time, organisations could learn from the interdependencies between intra- and interorganisational stakeholders, thereby supporting the monitoring of risks and uncertainties as well as the anticipation of potential consequences of changes in the ecosystem.

Originality/value – This paper introduces new thinking on the subject of business model innovation to the context of FM. It presents the external orientation of FM business models as a way to combine planned and emergent business model innovation through interorganisational collaboration and value creation in FM ecosystems.

The North Sea Offshore Wind Service Industry: Status, perspectives and a joint action plan

The Offshore Wind Service sector is about to establish itself as an industrial sector with an own identity, own organisation, and with large future challenges. The article introduces this new sector, including assessment of present and future market sizes. The overall aim of the research reported in this article was to increase the innovation capacity of the European offshore wind servicing (OWS) sector by establishing cross-regional cooperation and intensifying the relationship between research and the offshore wind industry. The article uses the concept of innovation system foresight (ISF). The linking of the two concepts of foresight and innovation systems has been explored by several studies, but ISF takes a further integration of the two concepts. The article presents a set of concrete actions at multiple levels to support the development of the offshore wind service sector. The findings provides an input for a concerted effort for supporting both the offshore wind development and the emerging clusters of offshore wind services around the North Sea. In addition, the article addresses the value of the ISF approach to such policy development.

Use of Input–Output Analysis in LCA

Input–output analysis can be used as a tool for complementing the traditionally process-based life cycle assessment (LCA) with macroeconomic data from the background systems. Properly used, it can result in faster and more accurate LCA. It also provides opportunities for streamlining the LCA inventory collection and focusing resources. This chapter reviews the main uses of input–output analysis (IO) to ensure consistent system boundaries, to evaluate the completeness of an LCA study and to form a basis for in-depth inventory collection. The use of IO as a data source for social and economic sustainability metrics is also discussed, as are the limitations of the approach. All aspects are demonstrated through examples and references both to recent scientific literature and publicly available datasets are provided. The aim of the chapter is to present the basic tools for applying IO in practical LCA studies.
The accountability imperative for quantifying the uncertainty of emission forecasts: evidence from Mexico

Governmental climate change mitigation targets are typically developed with the aid of forecasts of greenhouse-gas (GHG) emissions. The robustness and credibility of such forecasts depends, among other issues, on the extent to which forecasting approaches can reflect prevailing uncertainties. We apply a transparent and replicable method to quantify the uncertainty associated with projections of gross domestic product growth rates for Mexico, a key driver of GHG emissions in the country. We use those projections to produce probabilistic forecasts of GHG emissions for Mexico. We contrast our probabilistic forecasts with Mexico’s governmental deterministic forecasts. We show that, because they fail to reflect such key uncertainty, deterministic forecasts are ill-suited for use in target-setting processes. We argue that (i) guidelines should be agreed upon, to ensure that governmental forecasts meet certain minimum transparency and quality standards, and (ii) governments should be held accountable for the appropriateness of the forecasting approach applied to prepare governmental forecasts, especially when those forecasts are used to derive climate change mitigation targets. POLICY INSIGHTS No minimum transparency and quality standards exist to guide the development of GHG emission scenario forecasts, not even when those forecasts are used to set national climate change mitigation targets. No accountability mechanisms appear to be in place at the national level to ensure that national governments rely on scientifically sound processes to develop GHG emission scenarios. Using probabilistic forecasts to underpin emission reduction targets represents a scientifically sound option for reflecting in the target the uncertainty to which those forecasts are subject, thus increasing the validity of the target. Setting up minimum transparency and quality standards, and holding governments accountable for their choice of forecasting methods could lead to more robust emission reduction targets nationally and, by extension, internationally.
Scenarios for sustainable heat supply and heat savings in municipalities - the case of Helsingør, Denmark

Local climate action is not only a domain of large cities, but also smaller urban areas that increasingly address climate change mitigation in their policy. The Danish municipality of Helsingør can achieve a substantial CO2 emissions reduction by transforming its heat supply and deploying heat savings. In this paper, we model the heating system of Helsingør, assess it from a simple socio- and private-economic perspective, develop future scenarios, and conduct an iterative process to derive a cost-optimal mix between district heating, individual heating and heat savings. The results show that in 2030 it is cost-optimal to reduce the heating demand by 20–39% by implementing heat savings, to deploy 32%–41% of district heating and to reduce heating-related CO2 emissions by up to 95% in comparison to current emissions. In 2050, the cost-optimal share of district heating in Helsingør increases to between 38 and 44%. The resulting average heating costs and CO2 emissions are found to be sensitive to biomass and electricity price. Although the findings of the study are mainly applicable for Helsingør, the combined use of the Least Cost Tool and modelling with energyPRO is useful in planning of heating and/or cooling supply for different demand configurations, geographical region and scale.

Indoor releases of organic chemicals encapsulated in solid materials are major contributors to human exposures and are directly related to the internal diffusion coefficient in solid materials. Existing correlations to estimate the diffusion coefficient are only valid for a limited number of chemical-material combinations. This paper develops and evaluates a quantitative property-property relationship (QPPR) to predict diffusion coefficients for a wide range of organic chemicals and materials. We first compiled a training dataset of 1103 measured diffusion coefficients for 158 chemicals in 32 consolidated material types. Following a detailed analysis of the temperature influence, we developed a multiple linear regression model to predict diffusion coefficients as a function of chemical molecular weight (MW), temperature, and material type (adjusted R² of 0.93). The internal validations showed the model to be robust, stable and not a result of chance correlation. The external validation against two separate prediction datasets demonstrated the model has good predicting ability within its applicability domain (R²ext > 0.8), namely MW between 30 and 1178 g/mol and temperature between 4 and 180 °C. By covering a much wider range of organic chemicals and materials, this QPPR facilitates high-throughput estimates of human exposures for chemicals encapsulated in solid materials.
Could baseline establishment be counterproductive for emissions reduction? Insights from Vietnam’s building sector

This article provides insights into the role of institutions involved in climate governance working towards a future low-carbon society at the national level, within the global climate change governance architecture. Specifically, it contributes to understanding the fragmented governance of energy efficiency policy in developing countries by focussing on Vietnam’s building sector, identifying key institutions related to underlying discourses, national and international power relations, resource distribution and coalitions. It uses the case of baseline setting in developing Nationally Appropriate Mitigation Actions (NAMAs) to illustrate institutional dynamics, nationally and transnationally, as well as to question whether demands for baseline setting achieve the ideal trade-off between actual GHG emissions reduction and institutionalized demands for accountability. The analysis reveals that, in addition to domestic efforts and challenges, the international agenda greatly influences the energy efficiency policy arena. The article presents lessons to be learnt about policy processes from the specific Vietnamese case, reflecting on the role of international actors and discourses in it. Finally, it argues for the abolition of baselines in favour of adequate monitoring and evaluation, from the perspective that requirement for deviation from fictitious baselines is unproductive and only serves an international techno-managerial discourse.

The reverse tragedy of the commons: an exploratory account of incentives for under-exploitation in an open innovation environment

This paper presents an empirical account of a phenomenon that we refer to as the ‘reverse tragedy of the commons’ in open innovation. The name signifies the ‘under-exploitation’ of intellectual property (IP) under weak appropriability. The name is this graphic because the tragedy is costly, and can also render IP effectively worthless and block innovation in the short to medium term. We propose that the tragedy is borne out of the interaction between enterprise characteristics, a competitive setting and the framework that is set by the policy intervention. This finding is pertinent to policy-makers with regard to the design of research, development and innovation instruments, as well as managers who must determine how to implement open practices in innovation.

Sensitivity-based research prioritization through stochastic characterization modeling

Product developers using life cycle toxicity characterization models to understand the potential impacts of chemical emissions face serious challenges related to large data demands and high input data uncertainty. This motivates greater focus on model sensitivity toward input parameter variability to guide research efforts in data refinement and design of experiments for existing and emerging chemicals alike. This study presents a sensitivity-based approach for estimating toxicity characterization factors given high input data uncertainty and using the results to prioritize data collection according to parameter influence on characterization factors (CFs). Proof of concept is illustrated with the UNEP-SETAC scientific consensus model USEtox.

Modelling of electricity savings in the Danish households sector: from the energy system to the end-user

In this paper, we examine the value of investing in energy-efficient household appliances from both an energy system and end-user perspectives. We consider a set of appliance categories constituting the majority of the electricity consumption in the private household sector, and focus on the stock of products which need to be replaced. First, we look at the energy system and investigate whether investing in improved energy efficiency can compete with the cost of electricity supply from existing or new power plants. To assess the analysis, Balmorel, a linear optimization model for the heat and power sectors, has been extended in order to endogenously determine the best possible investments in more efficient home appliances. Second, we propose a method to relate the optimal energy system solution to the end-user choices by incorporating consumer behaviour and electricity price addition due to taxes. The model is nonexclusively tested on the Danish energy system under different scenarios. Computational experiments show that several energy efficiency measures in the household sector should be regarded as valuable investments (e.g. an efficient lighting system) while others would require some form of support to become profitable. The analysis quantifies energy and economic savings from the consumer side and reveals the impacts on the Danish power system and surrounding countries. Compared to a business-as-usual energy scenario, the end-user attains net economic savings in the range of 30–40 EUR per year, and the system can benefit of an annual electricity demand reduction of 140–150 GWh. The paper enriches the existing literature about energy efficiency modelling in households, contributing with novel models, methods, and findings related to the Danish case.

Learning from CDM SD tool experience for Article 6.4 in the Paris Agreement
The Paris Agreement (PA) emphasizes the intrinsic relationship between climate change and sustainable development (SD) and welcomes the 2030 agenda for the global Sustainable Development Goals (SDGs). Yet, there is a lack of assessment approaches to ensure that climate and development goals are achieved in an integrated fashion and trade-
offs avoided. Article 6.4 of the PA introduces a new Sustainable Mitigation Mechanism (SMM) with the dual aim to contribute to the mitigation of greenhouse gas emissions and foster SD. The Kyoto Protocol’s Clean Development Mechanism (CDM) has a similar objective and in 2014, the CDM SD tool was launched by the Executive Board of the CDM to highlight the SD benefits of CDM activities. This article analyses the usefulness of the CDM SD tool for stakeholders and compares the SD tool’s SD reporting requirements against other flexible mechanisms and multilateral standards to provide recommendations for improvement. A key conclusion is that the Paris Agreement’s SMM has a stronger political mandate than the CDM to measure that SD impacts are ‘real, measurable and long-term’. Therefore, recommendations for an improved CDM SD tool are a relevant starting point to develop rules, modalities and procedures for SD assessment in Article 6.4 as well as for other cooperative mitigation approaches.

A Bayesian Additive Model for Understanding Public Transport Usage in Special Events

Public special events, like sports games, concerts and festivals are well known to create disruptions in transportation systems, often catching the operators by surprise. Although these are usually planned well in advance, their impact is difficult to predict, even when organisers and transportation operators coordinate. The problem highly increases when several events happen concurrently. To solve these problems, costly processes, heavily reliant on manual search and personal experience, are usual practice in large cities like Singapore, London or Tokyo. This paper presents a Bayesian additive model with Gaussian process components that combines smart card records from public transport with context information about events that is continuously mined from the Web. We develop an efficient approximate inference algorithm using expectation propagation, which allows us to predict the total number of public transportation trips to the special event areas, thereby contributing to a more adaptive transportation system. Furthermore, for multiple concurrent event scenarios, the proposed algorithm is able to disaggregate gross trip counts into their most likely components related to specific events and routine behavior. Using real data from Singapore, we show that the presented model outperforms the best baseline model by up to 26 percent in R-2 and also has explanatory power for its individual components.

To reach the UN sustainable development goal, there is a need for comprehensive and robust tools to help decision-making identify the solutions that best support sustainable development. The decisions must have a system perspective, consider the life cycle, and all relevant impacts caused by the solution. Life Cycle Assessment (LCA) is a tool that has these characteristics and the ambition with this book is to offer a comprehensive and up-to-date introduction to the tool and its underlying methodological considerations and potential applications. The book consists of five parts. The first part introduces LCA. The second part is a text book aiming at university students from undergraduate to PhD level, and professionals from industry and within policy making. It follows ISO 14040/14044 structure, draws upon a variety of LCA methods published over the years, especially the ILCD, and offers prescriptions and recommendations for all the most important methodological choices that you meet when performing an LCA. The third part introduces applications of LCA and life cycle thinking by policy- and decision-makers in government and industry. The fourth part is a Cookbook guiding you through the concrete actions to undertake when performing an LCA. The fifth part contains some appendices. The book can be used as a text book, the chapter can be read as stand alone, and you can use the Cookbook as a manual on how to perform an LCA.
A Branch-and-Price algorithm for railway rolling stock rescheduling

How to best reschedule their fleet of rolling stock units during a disruption is an optimization problem regularly faced by railway operators. Despite the problem’s high complexity, it is still usually solved manually. In this paper we propose a path based mathematical formulation and solve it using a Branch-and-Price algorithm. We demonstrate that, unlike flow based approaches, our formulation is more easily extended to handle certain families of constraints, such as train unit maintenance restrictions. The proposed algorithm is benchmarked on several real-life instances provided by the suburban railway operator in Copenhagen, DSB S-tog. When used in combination with a lower bound method taken from the literature we show that near-optimal solutions to this rescheduling problem can be found within a few seconds. Furthermore, we show that the proposed methodology can be used, with minor modification, on a tactical planning level, where it produces near-optimal rolling stock schedules in minutes of CPU time.
A Branch-and-Price Approach to the Feeder Network Design Problem

In this paper we consider the problem of designing a container liner shipping feeder network. The designer has to choose which port to serve during many rotations that start and end at a central hub. Many operational characteristics are considered, such as variable leg-by-leg speeds and cargo transit times. Realistic instances are generated from the LinerLib benchmark suite. The problem is solved with a branch-and-price algorithm, which can solve most instances to optimality within one hour. The results also provide insights on the cost structure and desirable features of optimal routes. These insights were obtained by means of an analysis where scenarios are generated varying internal and external conditions, such as fuel costs and port demands.

A case study of life cycle impacts of small-scale fishing techniques in Thailand

Fish provides an important source of protein, especially in developing countries, and the amounts of fish consumed are increasing worldwide (mostly from aquaculture). More than half of all marine fish are caught by small-scale fishery operations. However, no life cycle assessment (LCA) of small-scale fisheries and no LCA of marine fishery operations in Asia (Thailand) exists today. We perform LCAs to compare the impacts of three different fishing techniques: crab gill-nets, squid traps, and fish traps. Primary data sourced from four different fishers were used. We distinguished the life cycle inventories for three different seasons (northeast monsoon, southwest monsoon and pre-monsoon), since the time spent on the water and catch varied significantly between the seasons. Our results showed the largest impacts from artisanal fishing operations affect climate change, human toxicity, and fossil and metal depletion. Our results are, in terms of global warming potential, comparable with other artisanal fisheries. Between different fishing operations, impacts vary between a factor of 2 (for land transformation impacts) and up to a factor of more than 20 (fossil fuel depletion and marine eutrophication). This shows that the way in which operations are performed have a very strong influence on results. Seasonality plays a relevant role for the assessment. Our results highlight that it is important to account for seasonal aspects in LCAs. We encourage a continual effort for collecting and modeling inventory processes, as well as making...
them available, in order to guarantee that LCA studies outside of Europe can be performed more easily.

**Accelerating time to benefit: Deconstructing innovative organizational practices in five projects**

Despite the ubiquitous pressure for speed, our approaches to accelerate projects remain constrained to the old-fashioned understanding of the project as a vehicle to deliver products and services, not value. This article explores an attempt to accelerate time to benefit. We describe and deconstruct the implementation of a large intervention undertaken in five project-based organizations in Denmark – the Project Half Double where the same project methodology has been applied in five projects, each of them in five distinct organizations in Denmark, as a bold attempt to realize double the benefit in half of the time. Although all cases valued speed and speed to benefit, and implemented most practices proposed by the methodology, only three of the five projects were more successful in decreasing time to speed. Based on a multi-case study comparison between these five different projects and their respective organizations, we propose five complementary explanations for the different results.

Accuracy of young male drivers’ self-assessments of driving skill

Accurate self-assessment of skill is important because it creates an appropriate level of confidence and hence behaviour. Inaccurate self-assessment of driving ability has been linked to reckless driving and accidents. Inaccurate self-assessment of driving skills may be a contributing factor to the over-representation of young male drivers in accident statistics. Most previous research on self-assessment of driving skills did not compare self-reported skills to objectively measured driving skills, so the aims of this study were: (1) to test the accuracy of young male drivers’ self-assessments of specific driving skills by comparing them with performance in a driving simulator; (2) to test whether self-assessment accuracy varied with driving skill, driving experience and sensation-seeking propensity. We found that young male drivers’ self-assessments were inconsistent with their driving performance, and that this inconsistency varied with driving skill, driving experience and sensation-seeking propensity. Groups with particularly inaccurate self-assessments are at high risk, because of their relative lack of skill, high mileage and sensation-seeking propensity. Self-assessments of hazard prediction and detection skills were particularly inaccurate. Understanding self-assessments of driving skill is crucial, but further studies are needed to allow preventive policies and interventions to take factors affecting self-assessments into account.
A choice function hyper-heuristic framework for the allocation of maintenance tasks in Danish railways

A new signalling system in Denmark aims at ensuring fast and reliable train operations, however imposes very strict time limits on recovery plans in the event of failure. As a result, it is necessary to develop a new approach to the entire maintenance scheduling process. In the largest region of Denmark, the Jutland peninsula, there is a decentralised structure for maintenance planning, whereby the crew start their duties from their home locations rather than starting from a single depot. In this paper, we allocate a set of maintenance tasks in Jutland to a set of maintenance crew members, defining the sub-region that each crew member is responsible for. Two key considerations must be made when allocating tasks to crew members. Firstly a fair balance of workload must exist between crew members and secondly, the distance between two tasks in the same sub-region must be minimised, in order to facilitate quick response in the case of unexpected failure. We propose a perturbative selection hyper-heuristic framework to improve initial solutions by reassigning outliers, those tasks that are far away, to another crew member at each iteration, using one of five low-level heuristics. Results of two hyper-heuristics, using a number of different initial solution construction methods are presented over a set of 12 benchmark problem instances.

Addressing Energy System Modelling Challenges: The Contribution of the Open Energy Modelling Framework (oemof)

The process of modelling energy systems is accompanied by challenges inherently connected with mathematical modelling. However, due to modern realities in the 21st century, existing challenges are gaining in magnitude and are supplemented with new ones. Modellers are confronted with a rising complexity of energy systems and high uncertainties on different levels. In addition, interdisciplinary modelling is necessary for getting insight in mechanisms of an integrated world. At the same time models need to meet scientific standards as public acceptance becomes increasingly important. In this intricate environment model application as well as result communication and interpretation is also getting more difficult.

In this paper we present the open energy modelling framework (oemof) as a novel approach for energy system modelling and derive its contribution to existing challenges. Therefore, based on literature review, we outline challenges for energy system modelling as well as existing and emerging approaches. Based on a description of the philosophy and elementary structural elements of oemof, a qualitative analysis of the framework with regard to the challenges is undertaken. Inherent features of oemof such as the open source, open data, non-proprietary and collaborative modelling approach are preconditions to meet modern realities of energy modelling. Additionally, a generic basis with an object-oriented implementation allows to tackle challenges related to complexity of highly integrated future energy systems and sets the foundation to address uncertainty in the future. Experiences from the collaborative modelling approach can enrich interdisciplinary modelling activities.

Our analysis concludes that there are remaining challenges that can neither be tackled by a model nor a modelling framework. Among these are problems connected to result communication and interpretation.

A dynamic approach to real-time performance measurement in design projects

Recent developments in engineering design management point to the need for more dynamic, fine-grain measurement approaches able to deal with multi-dimensional, cross-level process performance in product design. Thus, this paper proposes a new approach to the measurement and management of individual and teamwork performance in engineering design projects. This integrates multiple, previously disparate, aspects of design management and performance measurement theory in a single framework. Further, a fully realised performance measurement approach is developed, which complements existing management strategies. This framework is synthesised from an extensive review and illustrated via an in-depth case study. As such, this work contributes to performance measurement theory in engineering design and has significant implications for both engineering design research and industry.
A dynamic programming approach for quickly estimating large network-based MEV models

We propose a way to estimate a family of static Multivariate Extreme Value (MEV) models with large choice sets in short computational time. The resulting model is also straightforward and fast to use for prediction. Following Daly and Bierlaire (2006), the correlation structure is defined by a rooted, directed graph where each node without successor is an alternative. We formulate a family of MEV models as dynamic discrete choice models on graphs of correlation structures and show that the dynamic models are consistent with MEV theory and generalize the network MEV model (Daly and Bierlaire, 2006). Moreover, we show that these models can be estimated quickly using the concept of network flows and the nested fixed point algorithm (Rust, 1987). The main reason for the short computational time is that the new formulation allows to benefit from existing efficient solution algorithms for sparse linear systems of equations. We present numerical results based on simulated data with varying number of alternatives and nesting structures. We estimate large models, for example, a cross-nested model with 200 nests and 500,000 alternatives and 210 parameters that needs between 100–200 iterations to converge (4.3 h on an Intel(R) 3.2 GHz machine using a non-parallelized code). We also show that our approach allows to estimate a cross-nested logit model of 111 nests with a real data set of more than 100,000 observations in 14 h.

A Framework for Determining Product Modularity Levels

The application of modular products is seen as an important enabler for delivering customized products competitively. However, many companies struggle to find ways to implement modular products in a manner that suits their particular business. The literature includes examples of how modular products have been implemented in specific types of companies (mostly mass producers), but little guidance exists on how to identify the right level of modularity for other types of companies (such as engineer-to-order companies). In this article, we address this gap by suggesting a framework that categorizes the different types of modularity, where the categories fit different types of companies. More specifically, we introduce The Modularity Application Matrix – a conceptual tool that leads to a better understanding of partial modularization in relation to products. Through four case studies its application in practice is illustrated. This paper thereby contributes with new theoretical developments as well as a practical tool for practitioners in industries using partial modularization, such as, for example, the construction and building industry.

A Framework for International Location Decisions for Manufacturing Firms Published in Production Engineering

The purpose of this paper is to address current shortcomings in international location decisions (ILD), which were identified through an exploratory study, by developing a model that addresses previous limitations in research and encapsulate an adequate theories and frameworks. Based on insights from an exploratory study on 17 Danish manufacturing firms and a literature review of over a hundred publications, the Scope Model was developed with the MECE principles in mind in order to encompass all aspects as identified, while being supplemented by adequate tools and models in different phases of the ILD process. This paper presents an application-oriented model for facilitating ILDs in manufacturing firms, which is unique in its way of being exhaustive and yet able to decompose the ILD problem in different
A Framework for Operational Due Diligence in Mergers and Acquisitions
The number of mergers and acquisitions (M&As) has over the last five years increased greatly (Institute of Mergers, Acquisitions and Alliances, 2016). Furthermore, private equity professionals point to operational performance gains to drive an acquisition decision and attribute cost reductions as the most important lever for value creation, after a private equity firm acquires a company (PwC, 2016). However, the overall success rate of M&A activity remains low and the approach to understand an acquisition target’s operating model remains non-exhaustive and unstandardized. This paper investigates the pivotal determinants for assessing operational performance and identifying improvement potentials in an acquisition target. The research question is: “What are the fundamental operational determinants influencing the acquisition decision for private equity firms in the due diligence phase?” This paper presents an end-to-end framework which functions as a dynamic platform that simplifies the approach to conducting an operational due diligence (ODD). The framework focuses on identification and assessment of current operational performance and improvement drivers in the pre-acquisition phase.

A framework of knowledge creation processes in participatory simulation of hospital work systems
Participatory simulation (PS) is a method to involve workers in simulating and designing their own future work system. Existing PS studies have focused on analysing the outcome, and minimal attention has been devoted to the process of creating this outcome. In order to study this process, we suggest applying a knowledge creation perspective. The aim of this study was to develop a framework describing the process of how ergonomics knowledge is created in PS. Video recordings from three projects applying PS of hospital work systems constituted the foundation of process mining analysis. The analysis resulted in a framework revealing the sources of ergonomics knowledge creation as sequential relationships between the activities of simulation participants sharing work experiences; experimenting with scenarios; and reflecting on ergonomics.
consequences. We argue that this framework reveals the hidden steps of PS that are essential when planning and facilitating PS that aims at designing work systems.

A hybrid Constraint Programming/Mixed Integer Programming framework for the preventive signaling maintenance crew scheduling problem
A railway signaling system is a complex and interdependent system which should ensure the safe operation of trains. We introduce and address a mixed integer optimisation model for the preventive signal maintenance crew scheduling problem in the Danish railway system. The problem contains many practical constraints, such as temporal dependencies between crew schedules, the splitting of tasks across multiple days, crew competency requirements and several other managerial constraints. We propose a novel hybrid framework using Constraint Programming (CP) to generate initial feasible solutions to feed as ‘warm start’ solutions to a Mixed Integer Programming (MIP) solver for further optimisation. We apply the CP/MIP framework to a section of the Danish rail network and benchmark our results against both direct application of a MIP solver and modelling the problem as a Constraint Optimisation Problem (COP). Whereas the current practice of using a general purpose MIP solver is only able to solve instances over a two-week planning horizon, the hybrid framework generates good results for problem instances over an eight-week period. In addition, the use of a MIP solver to improve the initial solutions generated by CP is shown to be vastly superior to solving the problem as a COP.
Air Quality Monitoring System and Benchmarking

Air quality monitoring has become an integral part of smart city solutions. This paper presents an air quality monitoring system based on Internet of Things (IoT) technologies, and establishes a cloud-based platform to address the challenges related to IoT data management and processing capabilities, including data collection, storage, analysis, and visualization. In addition, this paper also benchmarks four state-of-the-art database systems to investigate the appropriate technologies for managing large-scale IoT datasets.

A life cycle assessment of poly-hydroxybutyrate extraction from microbial biomass using dimethyl carbonate

Poly-hydroxyalkanoates are an example of biodegradable and biocompatible polymers, produced from renewable raw materials. With respect to other bioplastics the market share of poly-hydroxyalkanoates is still limited because of their commercial costs. To develop more cost-effective processes, a multilevel approach is usually undertaken combining innovative, cheaper and more effective microbial cultivation with safe and cheap extraction and purification methodologies. This study assesses the potential life cycle environmental impacts related to a novel protocol poly-hydroxyalkanoates extraction based on dimethyl carbonate in comparison to the use of halogenated hydrocarbons (in particular 1,2-dichloroethane). Four scenarios are analysed for the dimethyl carbonate protocol considering: extraction from microbial slurry or from dried biomass, and recovery by solvent evaporation or polymer precipitation. The life cycle assessment demonstrates that the environmental performances of dimethyl carbonate-based protocols are far better than those of the most comparative process using the halogenated hydrocarbons. The scenario that foresees the extraction of dried biomass and recovers solvent by evaporation appears to be the most promising in terms of environmental sustainability performance.

A matheuristic for the Cargo Mix Problem with Block Stowage

The cargo-mix problem aims at selecting the amount of containers of a given type to load on a vessel. In this article we present an extended definition that includes the analysis of a circular route with draft restrictions, limitations on expected cargo and the use of a block stowage strategy. A compact formulation of the problem based on the state-of-the-art heuristic decomposition is shown not to be able to solve the extended problem, thus a matheuristic approach is presented that can achieve high quality results in a matter of seconds.

A method for Effect Modifier Assessment in ergonomic intervention research – The EMA method

Purpose: Intervention research includes studies in which researchers arrange (or follow) changes in working conditions to determine the effects on risk factor, health and/or performance. Often this research takes place at workplaces and not in a controlled laboratory environment. Effects may thus be due to other factors in addition to the intervention – i.e. effect
modifiers. These need to be identified and assessed in terms of potential impact on studied outcomes before proper inference can be drawn. We present a method to estimate potential effects of modifiers in intervention research.

**Methodology:**

The EMA method is a type of group interview including 3-6 employees representing the occupational groups in the investigated organization. With reference to the investigated period they are asked to recall important changes/events in and around the organization; 1) in general, 2) in work processes and equipment and 3) regarding their work environment. In each step the participants write their individual answers on post-it notes which are then discussed in plenum, one at a time, and placed on a timeline. All identified events are assessed as due to the investigated intervention(s) or other causes (“effect modifiers”). Their impact on the outcomes is estimated by triangulation. Following the workshop, events are entered into a database and analyzed. Results: Preliminary evaluations of the method suggest that it offers a relevant overview of potential effect modifiers. Limitations: Further validation is needed. Implications: Using the EMA-method seems to facilitate proper inference regarding the impact of a workplace intervention. Originality: The EMA-method is a novel and systematic approach to estimate potential effect modifiers.

**A multiple ship routing and speed optimization problem under time, cost and environmental objectives**

The purpose of this paper is to investigate a multiple ship routing and speed optimization problem under time, cost and environmental objectives. A branch and price algorithm as well as a constraint programming model are developed that consider (a) fuel consumption as a function of payload, (b) fuel price as an explicit input, (c) freight rate as an input, and (d) in-transit cargo inventory costs. The alternative objective functions are minimum total trip duration, minimum total cost and minimum emissions. Computational experience with the algorithm is reported on a variety of scenarios.

Analysing improvements to on-street public transport systems: a mesoscopic model approach

Light rail transit and bus rapid transit have shown to be efficient and cost-effective in improving public transport systems in cities around the world. As these systems comprise various elements, which can be tailored to any given setting, e.g. pre-board fare-collection, holding strategies and other advanced public transport systems (APTS), the attractiveness of such systems depends heavily on their implementation. In the early planning stage it is advantageous to deploy simple and transparent models to evaluate possible ways of implementation. For this purpose, the present study develops a mesoscopic model which makes it possible to evaluate public transport operations in details, including dwell times, intelligent traffic signal timings and holding strategies while modelling impacts from other traffic using statistical distributional data thereby ensuring simplicity in use and fast computational times. This makes it appropriate for analysing the impacts of improvements to public transport operations, individually or in combination, in early planning stages. The paper presents a joint measure of reliability for such evaluations based on passengers’ perceived travel time by considering headway time regularity and running time variability, i.e. taking into account waiting time and in-vehicle time. The approach was applied on a case study by assessing the effects of implementing segregated infrastructure and APTS elements, individually and in combination. The results showed that the reliability of on-street public transport operations mainly depends on APTS elements, and especially holding strategies, whereas pure infrastructure improvements induced travel time reductions. The results further suggested that synergy effects can be obtained by planning on-street public transport coherently in terms of reduced travel times and increased reliability.

An Empirical Comparison of Algorithms to Find Communities in Directed Graphs and Their Application in Web Data Analytics

Detecting communities in graphs is a fundamental tool to understand the structure of Web-based systems and predict their evolution. Many community detection algorithms are designed to process undirected graphs (i.e., graphs with bidirectional edges) but many graphs on the Web—e.g., microblogging Web sites, trust networks or the Web graph itself—are often directed. Few community detection algorithms deal with directed graphs but we lack their experimental comparison. In this paper we evaluated some community detection algorithms across accuracy and scalability. A first group of algorithms (Label Propagation and Infomap) are explicitly designed to manage directed graphs while a second group (e.g., WalkTrap) simply ignores edge directionality; finally, a third group of algorithms (e.g., Eigenvector) maps input graphs onto undirected ones and extracts communities from the symmetrized version of the input graph. We ran our tests on both artificial and real graphs and, on artificial graphs, WalkTrap achieved the highest accuracy, closely followed by other algorithms; Label Propagation has outstanding performance in scalability on both artificial and real graphs. The Infomap algorithm showcased the best trade-off between accuracy and computational performance and, therefore, it has to be considered as a promising tool for Web Data Analytics purposes.

Anger expression among Danish cyclists and drivers: A comparison based on mode specific anger expression inventories
Based on the short form of the driving anger expression inventory (DAX-short, 15-item), the present study developed an adapted version of the DAX for cyclists (CAX, 14 items). The data basis was an online survey of 2000 inhabitants of Denmark. A principle component analysis on the translated DAX-short confirmed the 4-factor solution of the original study differentiating between (1) personal physical aggressive expression, (2) use of a vehicle to express anger, (3) verbal aggressive expression and (4) adaptive/constructive expression. In case of cycling, the factor “use of a vehicle to express anger” only included one item and was left out. Based on the results, reliable subscales were developed. Drivers scored higher in verbal aggressive expression than cyclists, while there was no significant difference in constructive expression. The subscales for drivers and cyclists showed significant relations to age, gender, self-reported aggressive behaviours and traffic fines: Women scored for instance lower in physical expression, while older people scored higher in constructive
expression. The effect of age and gender on anger expression among drivers and cyclists remained significant when controlling for exposure and other factors in linear regression analyses. These analyses also showed a relationship between a positive attitude towards driving and higher levels of anger expression among drivers, while this was not the case for cyclists.

An Integrated Framework for Life Cycle Engineering

Life Cycle Engineering (LCE) was introduced as a concept more than 24 years ago in order to address emerging concerns about environmental sustainability in engineering. A number of methods and tools have been introduced to operationalise the LCE concept, but since then, the scope of sustainability has broadened, and as a result, LCE has evolved in parallel with other disciplines with similar aims. Currently, in addition to LCE, there exist a number of concepts such as Industrial Ecology, Cleaner Production, Life Cycle Management (LCM), Industrial Symbiosis, and Circular Economy. As a result, orientation becomes challenging and a framework to integrate them is required. The paper aims to introduce an integrated framework for LCE defining the concept and its boundaries, and it argues for the need to reorientate LCE towards the environmental dimension of sustainability. Through an integrated top-down and bottom-up approach, the framework establishes a relationship between LCE and the other concepts and positions them relative to the planetary boundaries and the concept of absolute environmental sustainability. A Novel Smart Meter Controlling System with Dynamic IP Addresses
Smart meters are the electronic devices for measuring energy consumption in real time. Usually, static public IP addresses are allocated to realize the point-to-point (P2P) communication and remote controlling for smart metering systems. This, however, restricts the wide deployment of smart meters, due to the deficiency of public IP resources. This paper proposes a novel subscription-based communication architecture for the support of dynamic IP addresses and group controlling of smart meters. The paper evaluates the proposed architecture by comparing the traditional P2P architecture, and validate its effectiveness to interact with smart meters.

Applying boundary objects to create coherence between management decisions regarding prevention of Musculoskeletal Disorders and implemented changes
Purpose. This study aims to support social healthcare workplaces with methods to establish coherence between management decisions regarding prevention of Musculoskeletal Disorders (MSD) and the work related preventive changes implemented in the organization. The study builds on the known risk factors for developing MSD in combination with the theory of explication of tacit knowledge by the use of boundary objects (Carlile, 2002). Design/Methodology. Searching the literature of visual knowledge generating methods, we selected those who focus on the work process and relate to one or more of the risk factors of MSD. The search resulted in the following methods: Workbooks, Photo-Safari, Layout Games, Employee Exchange, Videos and the Fishbone workshop. Three Occupational Health and Safety Departments in municipalities and one hospital tested the methods, which several public workplaces will apply starting January 2017. Results. The identified visualization methods each addresses specific risk factors of MSD but when combined, they provide a holistic insight in to the work-related causes to MSD at the workplace. The new knowledge forms the basis for focused work-related preventive changes. The test participants found the methods applicable in relation to create coherence between strategy and practice. Research implications: Our preliminary results imply that visualization methods can generate new knowledge about work-related causes to MSD, identification of new preventive changes and how they link to the preventive MSD strategy. Originality/Value. The study investigates the application of boundary objects in the identification of causes and implementation of a preventive MSD strategy and work-related changes.
Applying lean thinking to risk management in product development
This paper re-conceptualizes risk management (RM) in product development (PD) through a lean thinking perspective. Arguably, risk management in PD projects became a victim of its own success. It is often implemented as a highly formalized, compliance driven activity, ending up disconnected from the actual value creation of the engineering task. Cost overrun, delay and low quality decision making is common in product development processes even if RM processes are in place. Product development is about reaching project objectives by gradually reducing uncertainty, but often fail to do so without delay or cost overrun. This paper explores the relationship between product development and risk management and proposes to make RM an integrated value adding part of PD. Through a literature review we identify the potential of re-conceptualizing RM through lean thinking. We then conceptualize an outline of how one could apply lean thinking to RM to create a simple, value focused and consensus forming perspective on how to make RM a meaningful part of PD.

A research agenda for a people-centred approach to energy access in the urbanizing global south
Energy access is typically viewed as a problem for rural areas, but people living in urban settings also face energy challenges that have not received sufficient attention. A revised agenda in research and practice that puts the user and local planning complexities centre stage is needed to change the way we look at energy access in urban areas, to understand the implications of the concentration of vulnerable people in slums and to identify opportunities for planned management and innovation that can deliver urban energy transitions while leaving no one behind. Here, we propose a research agenda focused on three key issues: understanding the needs of urban energy users; enabling the use of context-specific, disaggregated data; and engaging with effective modes of energy and urban governance. This agenda requires interdisciplinary scholarship across the social and physical sciences to support local action and deliver large-scale, inclusive transformations.
A review of measured bioaccumulation data in terrestrial plants for organic chemicals: Metrics, variability and the need for standardized measurement protocols: Review of bioaccumulation data in terrestrial plants

Quantifying the transfer of organic chemicals from the environment into terrestrial plants is essential for assessing human and ecological risks, using plants as environmental contamination biomonitor, and predicting phytoremediation effectiveness. Experimental data describing chemical uptake by plants are often expressed as ratios of chemical concentrations in the plant compartments of interest (e.g., leaves, shoots, roots, xylem sap) to that in the exposure medium (e.g., soil, soil pore water, hydroponic solution, air). These ratios are generally referred to as bioconcentration factors (BCFs) but have also been named for the specific plant compartment sampled, such as root concentration factors (RCFs), leaf concentration factors (LCFs), or transpiration stream (xylem sap) concentrations factors (TSCFs). We reviewed over 350 papers to develop a database with 7,049 entries of measured bioaccumulation data for 310 organic chemicals and 112 terrestrial plant species. Various experimental approaches have been used; therefore, inter-study comparisons and data quality evaluations are difficult. Key exposure and plant growth conditions were often missing, and units were often unclear or not reported. The lack of comparable high confidence data also limits model evaluation and development. Standard test protocols, or at a minimum, standard reporting guidelines, for the measurement of plant uptake data are recommended to generate comparable, high-quality data that will improve mechanistic understanding of organic chemical uptake by plants. A review of models for near-field exposure pathways of chemicals in consumer products

Exposure to chemicals in consumer products has been gaining increasing attention, with multiple studies showing that near-field exposures from products is high compared to far-field exposures. Regarding the numerous chemical-product combinations, there is a need for an overarching review of models able to quantify the multiple transfers of chemicals from products used near-field to humans. The present review therefore aims at an in-depth overview of modeling approaches for near-field chemical release and human exposure pathways associated with consumer products. It focuses on lower-tier, mechanistic models suitable for life cycle assessments (LCA), chemical alternative assessment (CAA) and high-throughput screening risk assessment (HTS). Chemicals in a product enter the near-field via a defined "compartment of entry", are transformed or transferred to adjacent compartments, and eventually end in a "human receptor compartment". We first focus on models of physical mass transfers from the product to 'near-field' compartments. For transfers of chemicals from article interior, adequate modeling of in-article diffusion and of partitioning between article surface and air/skin/food is key. Modeling volatilization and subsequent transfer to the outdoor is crucial for transfers of chemicals used
in the inner space of appliances, on object surfaces or directly emitted to indoor air. For transfers from skin surface, models need to reflect the competition between dermal permeation, volatilization and fraction washed-off. We then focus on transfers from the 'near-field' to 'human' compartments, defined as respiratory tract, gastrointestinal tract and epidermis, for which good estimates of air concentrations, non-dietary ingestion parameters and skin permeation are essential, respectively. We critically characterize for each exposure pathway the ability of models to estimate near-field transfers and to best inform LCA, CAA and HTS, summarizing the main characteristics of the potentially best-suited models. This review identifies large knowledge gaps for several near-field pathways and suggests research needs and future directions.

A Scalable Smart Meter Data Generator Using Spark
Today, smart meters are being used worldwide. As a matter of fact smart meters produce large volumes of data. Thus, it is important for smart meter data management and analytics systems to process petabytes of data. Benchmarking and testing of these systems require scalable data, however, it can be challenging to get large data sets due to privacy and/or data protection regulations. This paper presents a scalable smart meter data generator using Spark that can generate realistic data sets. The proposed data generator is based on a supervised machine learning method that can generate data of any size by using small data sets as seed. Moreover, the generator can preserve the characteristics of data with respect to consumption patterns and user groups. This paper evaluates the proposed data generator in a cluster based environment in order to validate its effectiveness and scalability.

A Science Cloud for Smart Cities Research

Cities are densely populated and heavily equipped areas with a high level of service provision. Smart cities can use these conditions to achieve the goals of a smart society for their citizens. To facilitate such developments, the necessary IT-infrastructure has to be in place for supporting, amongst many other things, the whole lifecycle of big data management and analytics for research activities. At the Centre for IT-Intelligent Smart Energy for Cities, we have therefore been developing a flexible infrastructure, based on open sourcetechnologies. This paper presents this solution and its application in a city and building research.

Assessing the Added Value of Information Systems supporting facilities management business processes.

Purpose: To present a method for assessing the added value of Information Systems (IS), which are implemented to support the business processes in Facilities Management (FM). Theory: The method is based on a supply chain management model of FM, general value dimensions such as efficiency and effectiveness and the concepts of Value Adding Management (VAM) and Functional Affordances of IS. Design/methodology/approach: From case studies of IS implementation processes in FM in different countries, a general picture of the expressed added value of IS in FM was established. Based on this insight a method for assessing the added value of IS in FM was developed. The proposed method is applied to one of the cases. Findings: The paper analyses how a specific IS supports the management of a specific operational process – cleaning in an airport. The assessment shows that the IS definitely adds value to the cleaning process and because the resulting increase in user experience of the cleaning level is aligned with the strategy of the corporation, the IS also adds value to the primary process of the organisation. The analysis reveals that a well organised management setup is required to gain value from IS. It also illustrates that implementing IS includes both organisational and technological changes and demonstrates that the proposed assessment method is applicable to practice. Originality/value: This is the first paper using a supply chain management model of FM, general value dimensions, VAM and Functional Affordances to access the added value of IS in FM.

Assessing the edible city: Environmental implications of urban agriculture in the Northeast United States
One of the pivotal environmental challenges in the coming decades will be feeding an increasingly wealthy and populated planet in a sustainable manner. As industrialization and concomitant urbanization acts hitherto peripheral economies, much of this challenge will depend on the ability to support the nutritional demands of a global urban population in a fashion aligned with the biophysical capacity of the planet. Amongst the myriad of solutions proposed to guide humanity towards more environmentally sustainable food system, co-locating food production and consumption in cities is an area that has seen significant action in research, design and practice. In the Northeast United States, where per capita diets are amongst the most environmentally intensive globally, there is a growing interest in local food production as a way to reduce the ecological burdens of food demand. Urban farms and pro-urban agriculture planning agendas are proliferating throughout many of the region's cities, typically with urban agriculture's environmental sustainability evoked to varying degrees in support of these initiatives. However, environmental appraisals comparing urban and rural food production are scarce in existing literature, leaving a number of lingering questions surrounding urban agriculture's environmental performance. In a Northern context, it remains to be seen whether the benefits of reducing distance from farm to fork are outweighed by the energy demanded by yearround growing systems. Even if urban agriculture does provide leaner resource intensities at the farm scale, do these add up to meaningful shifts in a city's environmental footprint at the urban scale? The aim of this project was to begin removing these uncertainties using the Northeast United States as a case study, since cities within that region have some of the most vibrant and well-supported urban farming communities in the Global North. This report is comprised of six chapters that probe and add to our current understanding of urban food systems.

Assessing transformational change from institutionalising digital capabilities on implementation and development of Product-Service Systems: Learnings from the maritime industry

Digitization is rapidly reshaping industries and economic sectors. It enables novel Product-Service Systems (PSS) that transform customer/supplier relationships and introduces new value propositions. However, while opportunities for novel types of PSS arise, it is not clear how digitization and the institutionalisation of digital capabilities, particularly within the customer organisations, may affect implementation of PSS, potentially leading to transformational changes in the customer organisation. This paper examines one such potential transformational change from three complementary viewpoints – the resource based, the dynamic, and the relational viewpoint. It does so through action research study in the context of the maritime industry, which is particularly attractive for PSS offerings. The research methodology comprised a two-step action research process, focusing on both digitization and PSS development and implementation. The main findings are that rather than facilitating procurement to co-development of PSS, institutionalisation of digital capabilities facilitated development of PSS by stakeholders internal to the company, and strategic co-development with external stakeholders. The new digital capabilities circumvented cost barriers associated with the procurement of services from external stakeholders, supported process standardization - to the expense of process innovation-, and transformed the network that delivered PSS by closing opportunity gaps for externally procured services. Furthermore, the uptake of digital capabilities highlighted the importance of cost estimation in making the customer more responsive to threats and opportunities.
Assessing Transformational Change Potential in case of the Tunisian Cement NAMA

Assessing transformational change potential: the case of the Tunisian cement Nationally Appropriate Mitigation Action (NAMA)

To effectively address the root causes of carbon lock-in across developing countries, Nationally Appropriate Mitigation Actions (NAMAs) with transformational change characteristics are being supported by donors and finance mechanisms as a means to achieve ambitious nationally determined contributions (NDCs). However, there is still a scarcity of empirical studies on how transformational change policies and actions are designed and supported in practice. This article addresses such a gap in knowledge by combining theoretical insights from the multi-level perspective and transitions management literature to examine a donor-supported cement sector NAMA in Tunisia developed during 2012–2013. A narrative is constructed to analyse the adequacy of the NAMA design to promote structural shifts towards low carbon development in the cement sector. Data collection is based on semi-structured interviews and documentation gathered during field work in Tunisia 2014–2015. The study finds that the NAMA design is not likely to lead to transformational change of the cement sector, since underlying factors accounting for lock-in are not properly tackled. Although the NAMA has enabled new and promising sectoral partnerships across the cement sector, the analysis suggests that the NAMA’s transformational potential is currently limited by a number of factors not being adequately addressed. Measures are proposed to reorient the NAMA towards promoting system innovation, building on further research and experimentation with the policy entrepreneurial role of donors.

Assessment of stormwater management options in urban contexts using Multiple Attribute Decision-Making

This paper addresses the problem of selecting the most sustainable stormwater management alternative in developing countries in a dense urban context. Firstly, suitable Low Impact Development (LID) stormwater management measures for dense urban areas in developing countries were identified based on critical review of literature. Alternatives have been
formulated as varying percentages (degree of adoption) of these suitable measures to manage the stormwater sustainably. Further, a novel decision-making framework is developed which generates the hierarchy for selection of the most sustainable stormwater management alternative. Four main criteria (technical, economic, environmental and social) comprising three quantitative and eight qualitative indicators have been used for evaluating seven alternatives. The regional and local societal priorities are captured through criteria-weightings and are translated into a decision-making methodology. Experts’ opinions have been included using Analytical Hierarchy Process (AHP). One of the most widely used Multiple Attribute Decision-Making (MADM) method, TOPSIS, is used to rank the alternatives and to identify the most sustainable alternatives. Various scenarios to represent different stakeholders’ perspectives have been articulated. Alternative with medium level of cost implication and satisfactory level of performance is chosen by the decision making method in most of the scenarios. The proposed decision making approach can be used for selecting sustainable stormwater management options in densely populated areas of developing countries.

A Strategic View of University Timetabling

University Timetabling has traditionally been studied as an operational problem where the goal is to assign lectures to rooms and timeslots and create timetables of high quality for students and teachers. Two other important decision problems arise before this can be solved: what rooms are necessary, and in which teaching periods? These decisions may have a large impact on the resulting timetables and are rarely changed or even discussed. This paper focuses on solving these two strategic problems and investigates the impact of these decisions on the quality of the resulting timetables.

The relationship and differences between operational, tactical and strategic timetabling problems are reviewed. Based on the formulation of curriculum-based course timetabling and data from the Second International Timetabling Competition (ITC 2007), three new bi-objective mixed-integer models are formulated. We propose an algorithm based on the -constraint method to solve them. The algorithm can be used to analyze the impact of having different resources available on most timetabling problems. Finally, we report results on how the three objectives - rooms, teaching periods and quality - influence one another.

A Survey of Scholarly Data: From Big Data Perspective

Recently, there has been a shifting focus of organizations and governments towards digitization of academic and technical documents, adding a new facet to the concept of digital libraries. The volume, variety and velocity of this generated data, satisfies the big data definition, as a result of which, this scholarly reserve is popularly referred to as big scholarly data. In order to facilitate data analytics for big scholarly data, architectures and services for the same need to be developed. The evolving nature of research problems has made them essentially interdisciplinary. As a result, there is a growing demand for scholarly applications like collaborator discovery, expert finding and research recommendation systems, in addition to several others. This research paper investigates the current trends and identifies the existing challenges in development of a big scholarly data platform, with specific focus on directions for future research and maps them to the different phases of the big data lifecycle.

A Survey on Robustness in Railway Planning

Planning problems in passenger railway range from long term strategic decision making to the detailed planning of operations. Operations research methods have played an increasing role in this planning process. However, recently more attention has been given to considerations of robustness in the quality of solutions to individual planning problems, and of operations in general. Robustness in general is the capacity for some system to absorb or resist changes. In the context of railway robustness it is often taken to be the capacity for operations to continue at some level when faced with a disruption such as delay or failure. This has resulted in more attention given to the inclusion of robustness measures and objectives in individual planning problems, and to the providing of tools to ensure operations continue under disrupted situations. In
this paper we survey the literature on robustness in railway planning problems, considering how robustness is conceptualized and modelled for the individual problems of railway, the degree to which an overall railway robustness concept is present, and consider the future directions of robustness in railway planning.

A system dynamics case study of resilient response to IP theft from a cyber-attack

Undesirable changes in supply chain physical operations derived from disruptions in the transmission or storage of digital information are reported daily despite the Information Technology (IT) protection available. Once a disruption materializes, the company losses will depend on the coherence and swiftness of the supply chain response (resilience). However, current resilience frameworks are qualitative, do not address evolution over time as a relevant aspect, and thus do not provide indications on how to design a resilient response. This paper contributes to closing this gap by developing a system dynamics model from an actual case of resilient response after a cyber-attack. Both casespecific and generic structures are extracted from the case data analysis, and a reaction mechanism is proposed that results in the observed behavior. The identification of these structures should eventually aid decision makers in the process of designing a resilient supply chain response.

Automated HAZOP revisited

Hazard and operability analysis (HAZOP) has developed from a tentative approach to hazard identification for process plants in the early 1970s to an almost universally accepted approach today, and a central technique of safety engineering. Techniques for automated HAZOP analysis were developed in the 1970s, but still have not displaced expensive manual approaches. Reasons for this were investigated and conclusions are drawn. The author's actual experience in applying automated HAZOP techniques over a period of more than 30 years is revisited, including results from several full-scale validation studies and many industrial applications. Automated techniques, when combined with manual approaches, were found to provide significant improvements in HAZOP quality and a limited but valuable improvement in efficiency.
Automatic Identification of Similarities Across Products to Improve the Configuration Process in ETO Companies

Engineer-To-Order (ETO) companies making complex products face the challenge of delivering highly customised products with high quality, affordable price and a short delivery time. To respond to these challenges, ETO companies strive to increase the commonality between different projects and to reuse product-related information. Therefore, ETO companies need to retrieve data about previously designed products and identify parts of the design that can be reused to improve the configuration process. This allows companies to reduce complexity in the product portfolio, decrease engineering hours and improve the accuracy of the product specifications. This article proposes a framework to identify and compare products’ similarities. The framework (1) identifies the most important product variables available in the Product Configuration System (PCS), (2) retrieves data of previously designed products in an Enterprise Resource Planning (ERP) system, (3) identifies a method to compare products based on the main products variables and (4) sets up an IT system (database) with data of the previously designed products to integrate with the PCS. The proposed approach (the framework and the IT system) is tested in an ETO company to evaluate the application of the framework and the IT system. We retrieved the needed data from the ERP system at the case company and developed the IT system in Microsoft Excel, which is integrated with the PCS.
Balancing Constraints and the Sweet Spot as Coming Topics for Creativity Research

The aim of this chapter is the introduction of two new concepts, ‘balancing constraints’ and ‘the sweet spot of creativity’, as promising new paths for creativity research. This is motivated by the fact that creativity research shows a growing interest in the fundamental entwinement of constraints and creativity, with skillful and innovative handling of constraints seen as a prerequisite for apt creative performance. Based on a brief review of current disparate conceptualizations of constraints as both enablers and restrainers of creative activities, we begin by proposing the unifying concept ‘creativity constraints’ to help establish common terminological ground. Since the presence of constraints change over time, we suggest the term ‘constrainedness’ to articulate this total constraint intensity at a given time. This allows us to introduce our main contribution, the concept ‘the sweet spot’, to address the salient situations where the creative practitioner can be said to experience the ‘right’ level of constrainedness conducive to optimum creative performance. We then proceed to consider how the sweet spot can be attained by balancing constraints, i.e., by manipulating the intensity of constrainedness. More concretely, this means by hardening or softening the constraints at hand, resulting in a higher or lower level of constrainedness. Finally, we discuss how future studies can employ and inform these new concepts, which we see as potentially rich for cross-disciplinary creativity research focusing on the essential entwinement of constraints and creativity.

Barriers for district heating as a source of flexibility for the electricity system

The Scandinavian countries Denmark, Norway and Sweden currently deploy large amounts of variable renewable energy (VRE) sources, especially wind power. This calls for additional flexibility in the power market. The right coupling to the underlying national and local district heating (DH) markets can generate large amounts of flexibility. However, regulatory barriers and different energy market designs may hinder the potential benefits from system integration, and lower the potential that can be realized. The Scandinavian countries have a large extension of DH with a good potential for providing flexibility services to the electricity market. We survey and discuss regulatory barriers and drivers for exploiting this potential for flexibility. Combined heat and power (CHP) is widely integrated in the power market, but it is threatened by low electricity prices due to the increasing amounts of wind power. Power-to-heat technologies, electric boilers and heat pumps are blocked by high tariffs and taxes. A calculation of the heat costs of
different DH technologies demonstrates that, under the present price and tax conditions in Denmark and Sweden, CHP and power-to-heat are unable to compete with heat-only boilers that use tax-free biomass.

Behavioural design: A process for integrating behaviour change and design
Nudge, persuasion, and the influencing of human behaviour through design are increasingly important topics in design research and in the wider public consciousness. However, current theoretical approaches to behaviour change have yet to be operationalized this in design process support. Specifically, there are few empirically grounded processes supporting designers in realising behaviour change projects. In response to this, 20 design projects from a case company are analysed in order to distil a core process for behavioural design. Results show a number of process stages and activities associated with project success, pointing to a new perspective on the traditional design process, and allowing designers to integrate key insights from behaviour change theory. Using this foundation we propose the Behavioural Design process.
Being, doing and leading in the project society

The last decades have seen a proliferation of projects across different contexts, from the building of an iconic venue to the planning of a family vacation. Building on Jensen (2009) work on the project society and Jensen et al (2016) articulation of projects as human conditions, this article explores strategies for living in the project society. Guided by the philosophical concepts of activity, time, space and relations, we explore the project society as an ideal type, in opposition to the disciplinary society. We discuss implications of being, doing and leading in a project society. Taken together this analysis describes some of the key challenges emerging from the project society and suggests some ideas and advices to fellow project man and woman, navigating in project society.

The work extends our understanding of projects beyond organizational settings – to a societal and individual level. We argue that, first, our growing and insightful body of literature on project organizing can become useful for each one of us as individuals navigating in project society. Second, it opens up to a more extensive empirical context – studying behaviour of people in projects, outside classic organizational settings. In this respect, the article serves as a basis for future research on living in the project society where nothing lasts forever but our projects define who we are and what we can become.

Benchmarking healthcare logistics processes: a comparative case study of Danish and US hospitals

Logistics processes in hospitals are vital in the provision of patient care. Improving healthcare logistics processes provides an opportunity for reduced healthcare costs and better support of clinical processes. Hospitals are faced with increasing healthcare costs around the world and improvement initiatives prevalent in manufacturing industries such as lean, business process reengineering and benchmarking have seen an increase in use in healthcare. This study investigates how logistics processes in a hospital can be benchmarked to improve process performance. A comparative case study of the bed logistics process and the pharmaceutical distribution process was conducted at a Danish and a US hospital. The case study results identified decision criteria for designing efficient and effective healthcare logistics processes. The most important decision criteria were related to quality, security of supply and employee engagement. Based on these decision criteria, performance indicators were developed to enable benchmarking of logistics processes in healthcare. The study contributes to the limited literature on healthcare logistics benchmarking. Furthermore, managers in healthcare logistics are provided with a list of decision parameters relevant for designing and benchmarking processes.

Benders' Decomposition for Curriculum-Based Course Timetabling

In this paper we applied Benders' decomposition to the Curriculum-Based Course Timetabling (CBCT) problem. The objective of the CBCT problem is to assign a set of lectures to time slots and rooms. Our approach was based on segmenting the problem into time scheduling and room allocation problems. The Benders' algorithm was then employed to generate cuts that connected the time schedule and room allocation. We generated only feasibility cuts, meaning that most of the solutions we obtained from a mixed integer programming solver were infeasible, therefore, we also provided a heuristic in order to regain feasibility.

We compared our algorithm with other approaches from the literature for a total of 32 data instances. We obtained a lower bound on 23 of the instances, which were at least as good as the lower bounds obtained by the state-of-the-art, and on eight of these, our lower bounds were higher. On two of the instances, our lower bound was an improvement of the
currently best-known. Lastly, we compared our decomposition to the model without the decomposition on an additional six instances, which are much larger than the other 32. To our knowledge, this was the first time that lower bounds were calculated for these six instances.

Between Indoor and Outdoor. Norwegian Perceptions of Well-Being in Energy Efficient Housing

An increased societal focus on energy efficiency has led to the development of new building concepts and standards in many countries, such as the passive house standard in Norway which implies a dense building envelope with restrictions on the use of glass and natural ventilation. Generally low-energy building concepts are based on a rational approach to comfort in housing limited to mainly measurable aspects. This, however, hardly reflects what makes residents feel comfortable at home, since it lacks a holistic understanding of residential well-being. Well-being is a complex and multifaceted concept that includes atmosphere and feeling at home. In a qualitative study of four Norwegian low-energy housing projects, we investigate and discuss the impact of visual and sensory qualities, like view, daylight and access to fresh air, on residential well-being. The study reveals that it is possible to achieve well-being in energy-efficient housing, but some practices jeopardize the energy-design concept and influence energy use. Residents find strategies to achieve well-being by opening windows and doors, despite restrictions on airing naturally. Access to daylight and view and the ability to open windows or balcony doors to let in air, smells and sounds from the outside are crucial for residents' well-being and thus important factors to consider when designing and building energy-efficient housing where people feel at home.

Beyond effectuation: Analysing the transformation of business ideas into ventures using actor-network theory*

Purpose
The purpose of this paper is to show that the entrepreneurial project ongoingly is transformed. Empirically, three defining junctions demonstrate the malleability of the entrepreneurial project in perpetual action, expanding beyond effectuation theory on what constitutes given means, affordable loss, and other key concepts from this theoretical perspective. Drawing upon actor-network theory (ANT), this study demonstrates how different framing and support devices implicate different human and non-human actors in changing interpositions within the entrepreneurial process.

Design/methodology/approach
This study uses a longitudinal case study design. The case provides an overview of a new business’s emergence based on three identified translations, each representing critical junctures in the business’s development. An ethnographic approach is selected, which combines observations with qualitative interviews. This design allows the authors to focus on how the project emerges and is continuously supported by allies but is sometimes not supported by various human and non-human actors.

Findings
This study demonstrates that the entrepreneurial project undertaken by the entrepreneurial network changes as new humans or non-humans become part of it. Including a resource in the network means simultaneously changing the network. This interactionism shows that what sparks interest or attracts resources to a business idea is not simply an influx of additional resources but is simultaneously a dynamic definition of the entrepreneurial endeavour.

Originality/value
This paper examines how ideas are transformed into business ventures by using the ANT to expand understanding from effectuation theory. This shows that means, for instance, are not given but are co-created by the process of translation. In addition, which losses are affordable can be determined by the process within which the entrepreneur frames the project and manages to associate allies within and into the network.

Bioenergy production and sustainable development: science base for policy-making remains limited
The possibility of using bioenergy as a climate change mitigation measure has sparked a discussion of whether and how bioenergy production contributes to sustainable development. We undertook a systematic review of the scientific literature to illuminate this relationship and found a limited scientific basis for policy-making. Our results indicate that knowledge on the sustainable development impacts of bioenergy production is concentrated in a few well-studied countries, focuses on environmental and economic impacts, and mostly relates to dedicated agricultural biomass plantations. The scope and methodological approaches in studies differ widely and only a small share of the studies sufficiently reports on context and/or baseline conditions, which makes it difficult to get a general understanding of the attribution of impacts. Nevertheless we identified regional patterns of positive or negative impacts for all categories – environmental, economic, institutional, social and technological. In general, economic and technological impacts were more frequently reported as positive, while social and environmental impacts were more frequently reported as negative (with the exception of impacts on direct substitution of GHG emission from fossil fuel). More focused and transparent research is needed to validate these patterns and develop a strong science underpinning for establishing policies and governance agreements that prevent/mitigate negative and promote positive impacts from bioenergy production.

Can carbon footprint serve as proxy of the environmental burden from urban consumption patterns?
Carbon footprint (CFP) is widely applied as an indicator when assessing environmental sustainability of products and services. The objective of the present study is to evaluate the validity of CFP as an overall environmental indicator for representing the environmental burden of residents from urbanized areas. Applying four different Life Cycle Impact Assessment (LCIA) methods, environmental impact profiles were determined for the consumption patterns of 1281 Danish urban residents. Six main consumption components were distinguished including road transport, air travel, food, accommodation (covering consumption of materials for the construction of dwellings) and use of energy in terms of thermal energy, and electricity. The results for the individual consumption components showed a strong correlation between CFP and nearly all other impact indicators for all the applied LCIA methods. However, upon aggregation of the indicator results across consumption components, the impact indicators for the total consumption showed no significant correlation between CFP and the other impact scores for any of the four impact assessment methods. These findings suggest that while CFP can be a good indicator of the environmental burden associated with specific activities, this is not the case for more complex activities (such as consumption patterns related to urban life styles). This conclusion discourages the use of CFP as a sustainability measure in relation to regulation of private or public consumption.
Can you design for Fidelity? How your intervention framework describes intended actions, participation and behavior

In recent years the term fidelity has been introduced within the field of organizational level interventions. Fidelity describes the extent to which the intervention has been implemented as it was originally intended, and is regarded critical for
determining the validity of the research results. The reason for introducing this term has been for researchers to be able to
conclude whether an intervention has worked as intended. In this paper we discuss the term fidelity in relation to the
concept of script analysis (Akrich 1994). We do this to question whether it is even relevant to discuss fidelity in
organizational level interventions. The concept of fidelity stems from clinical interventions although the concept has
developed over time (Bellg et al. 2004). Organizational level interventions differ from clinical interventions, as they are
more complex regarding both the “dose” given and the number and levels of participants involved at the same time.
Steering organizational level interventions in every detail and secure full fidelity or treatment integrity can thus seem
difficult. Organizational level intervention frameworks are often built on the designer’s experiences with previous
interventions as well as what have been reported as best practice. The designer thus has a large role in making the
intervention work – he or she can design intended actions, participation and behavior into the framework. The notion script
can help explain the designer’s role. A script is the designer’s presumptions, visions and predictions about how the
framework will interact with the intervention participants. As derived concepts Akrich (1994) introduces ‘in-scription’ and
‘de-scription’. Where ‘in-scription’ is the limitations and constraint that the intervention designer in-scribe in the framework,
and ‘de-scription’ is how the intervention participants interpret the framework and adjust the framework to the organization.

Can you put too much on your plate? Uncertainty exposure in servitized triads
Purpose: Servitization increases the uncertainty exposure of provider firms due to the operational differences between
services and production which is further increased when operations are set in triads. This paper analyses the uncertainty
exposure in servitized triads and explores suitable organisational responses.

Design/methodology/approach: A conceptual frame is defined detailing three uncertainty types (environmental,
organisational and relational uncertainty) and suitable organisational responses to these. This frame guided the analysis of
indepth case evidence from a cross-national servitized triad in a European-North African set-up which was collected
through 29 semi-structured interviews and secondary data.

Findings: The empirical study identified the existence of the three uncertainty types and directional knock-on effects
between them. Specifically, environmental uncertainty created organisational uncertainty which in turn created relational
uncertainty. The uncertainty types were reduced through targeted organisational responses where formal relational
governance reduced environmental uncertainty, service capabilities reduced organisational uncertainty, and informal
relational governance reduced relational uncertainty. The knock-on effects were reduced through organisational and
relational responses.

Originality: This paper makes two contributions. First, a structured analysis of the uncertainty exposure in servitized triads
is presented which shows the existence of three individual uncertainty types and the knock-on effects between
them. Second, organisational responses to reduce the three uncertainty types individually and the knock-on effects
between them are presented.

Capacity Remuneration Mechanisms for Reliability In the Integrated European Electricity Market: Effects on Welfare and Distribution through 2023
A reduced attractiveness of investments in reliable fossil power plants in liberalized markets on the background of a transition towards renewable energies has brought a discussion on capacity policies to Europe. I develop a partial equilibrium model to compare effects of three polar capacity remuneration mechanisms (CRMs) based on the assumption that a CRM is indicated. A strategic reserve (SR) policy with administratively set capacity targets, a capacity market (CM) based on public procurement, and a decentralized reserve market with the obligation of generators to finance reserves in relation to their peak supply (RM). Substantial differences of policies arise across countries and regarding consumers and producers due to power plant structures. By 2023, we find the decentralized RM to induce least pronounced distributional effects and only modest welfare reductions, while SR and CM induce higher losses. In the longer term until 2033, welfare results differ less pronounced, although the RM is most friendly to consumers. A robust policy conclusion has to pay attention to further aspects concerning the environment and technological developments.
Catalysing low cost green technologies for sustainable water service delivery in Kenya: Feasibility Study Report

Since 1974, the government of Kenya has recognised water supplies as critical for poverty reduction and development. Kenya’s economic and social development Vision 2030 emphasises the need for adequate and sustainable provision of water supply and sanitation services, with a target to achieve universal access by 2030. However, thus far most water
development targets have not been achieved. Improvement has been much slower in rural and low income urban areas, and the current funding level is inadequate to achieve universal access by 2030. Over the years, official effort have been complemented through non-programmatic community and self-help action, but many projects quickly deteriorate after implementation and are rarely functioning 5 years after implementation. Consequently, water services available for the poor in Kenya are often inadequate, unsafe and unsustainable. Weak attention to planning, standards and operations and maintenance, including source and cost of energy in rural and peri-urban water supplies is a key challenge to functionality and sustainability.

Characterization of annual disease progression of multiple sclerosis patients: A population-based study
Previous research characterizing factors influencing multiple sclerosis (MS) disease progression has typically been based on time to disease milestones (Kaplan-Meier, Cox hazard regression, etc.). A limitation of these methods is the handling of the often large groups of patients not reaching the milestone. To characterize clinical factors influencing MS disease progression as annual transitions from each Expanded Disability Status Scale (EDSS). The annual progression of 11,964 patients from the Swedish MS Registry was analysed with 10 multinomial logistic regressions, that is, one for transition from each full EDSS with explanatory variables age, sex, age at onset, time in current EDSS, highest prior EDSS, MS course and treatment. All factors (except sex) investigated had statistically significant impacts on transitions from at least one EDSS. However, significance and size of the effect are dependent on the EDSS state of the patient. Greater age, longer time in a state, highest prior EDSS, having progressive MS and treatment had significant impacts, whereas age at onset had minor impact. Our study confirms that established factors associated with MS disease worsening in time to disease milestones also have impacts on annual progression. This approach adds granularity to what EDSS these factors have an influence.

Characterization of waterborne nitrogen emissions for marine eutrophication modelling in life cycle impact assessment at the damage level and global scale

Current life cycle impact assessment (LCIA) methods lack a consistent and globally applicable characterization model relating nitrogen (N, as dissolved inorganic nitrogen, DIN) enrichment of coastal waters to the marine eutrophication impacts at the endpoint level. This paper introduces a method to calculate spatially explicit characterization factors (CFs) at endpoint and damage to ecosystems levels, for waterborne nitrogen emissions, reflecting their hypoxia-related marine eutrophication impacts, modelled for 5772 river basins of the world.

Exposure to fine particulate matter (PM$_{(2.5)}$) from indoor and outdoor sources is a leading environmental contributor to global disease burden. In response, we established under the auspices of the UNEP/SETAC Life Cycle Initiative a coupled indoor-outdoor emission-to-exposure framework to provide a set of consistent primary PM$_{(2.5)}$ aggregated exposure factors. We followed a matrix-based mass balance approach for quantifying exposure from indoor and ground-level urban and rural outdoor sources using an effective indoor-outdoor population intake fraction and a system of archetypes to represent different levels of spatial detail. Emission-to-exposure archetypes range from global indoor and outdoor averages, via archetypal urban and indoor settings, to 3646 real-world cities in 16 parameterized sub-continental regions. Population intake fractions from urban and rural outdoor sources are lowest in Northern regions and Oceania and highest in Southeast Asia with population-weighted means across 3646 cities and 16 sub-continental regions of, respectively, 39 ppm (95% confidence interval: 4.3–160 ppm) and 2 ppm (95% confidence interval: 0.2–6.3 ppm). Intake fractions from residential and occupational indoor sources range from 470 ppm to 62,000 ppm, mainly as function of air exchange rate and occupancy. Indoor exposure typically contributes 80–90% to overall exposure from outdoor sources. Our framework facilitates improvements in air pollution reduction strategies and life cycle impact assessments.

CITIESData: a smart city data management framework

Smart city data come from heterogeneous sources including various types of the Internet of Things such as traffic, weather, pollution, noise, and portable devices. They are characterized with diverse quality issues and with different types of sensitive information. This makes data processing and publishing challenging. In this paper, we propose a framework to streamline smart city data management, including data collection, cleansing, anonymization, and publishing. The paper classifies smart city data in sensitive, quasi-sensitive, and open/public levels and then suggests different strategies to process and publish the data within these categories. The paper evaluates the framework using a real-world smart city data set, and the results verify its effectiveness and efficiency. The framework can be a generic solution to manage smart city data.

This paper examines some of the most common frameworks available to companies in implementing circular economy strategies, i.e. the Cradle-to-Cradle design protocol, the Material Circularity Indicator and the Life Cycle Sustainability Assessment framework intended as a combination of Life Cycle Assessment, Environmental Life Cycle Costing and Social Life Cycle Assessment. We focus on the packaging sector and use the case of closed-loop aluminium can supply to illustrate the benefits and limitations of combining some of these frameworks. Our recommendation is to use the Life Cycle Sustainability Assessment framework to evaluate circularity strategies, since it is the most comprehensive and still operational framework and best at preventing burden shifting between stakeholders in the value chain.
Clustering of maintenance tasks for the Danish railway system

Standardisation of the European rail traffic signalling system is an ongoing project for faster travel within the EU, which entails very strict time limits and constraints on recovery operations. Denmark will be the first country to upgrade its entire signalling system to implement the new standards. In this paper, we present a mathematical model for allocation of maintenance tasks to maintenance team members, which is a variant of the Generalized Assignment Problem. The aim is to optimise the following three criteria: (i) the total distance travelled from depots to tasks, (ii) the maximal distance between any maintenance task and its allocated crew member, and (iii) the imbalance in workload among crew members. As test cases, we use a set of instances that simulate the distribution of tasks in the Jutland peninsula, the largest region of Denmark.

Collaborative Filtering Fusing Label Features Based on SDAE

Collaborative filtering (CF) is successfully applied to recommendation system by digging the latent features of users and items. However, conventional CF-based models usually suffer from the sparsity of rating matrices which would degrade model’s recommendation performance. To address this sparsity problem, auxiliary information such as labels are utilized. Another approach of recommendation system is content-based model which can’t be directly integrated with CF-based model due to its inherent characteristics. Considering that deep learning algorithms are capable of extracting deep latent features, this paper applies Stack Denoising Auto Encoder (SDAE) to content-based model and proposes LCF(Deep Learning for Collaborative Filtering) algorithm by combing CF-based model which fuses label features. Experiments on real-world data sets show that DLCF can largely overcome the sparsity problem and significantly improves the state of art approaches.
Combined Life Cycle Assessment and Life Cycle Costing in the Eco-Care-Matrix: A case study on the performance of a modernized manufacturing system for glass containers

The objects of Life Cycle Assessment (LCA) case studies are often individual components or individual products. Studies focusing on larger industrial manufacturing systems are relatively rare. The purpose of this case study was to assess environmental and cost-related performance of an updated complex manufacturing system for glass containers (i.e. jars, glass bottles, etc.) compared to the predecessor manufacturing system. The objective was also to identify the most relevant drivers for the environmental and the cost profile of the system solution in application context by the means of Life Cycle Assessment, as well as Life Cycle Costing (LCC). The results were then to be displayed in an Eco-Care-Matrix (ECM) in order to quantitatively visualize the improvements when comparing the updated manufacturing system to the previous one and they were to be discussed in terms of (i) ecodesign levers, (ii) efficiency of the LCA process and (iii) their relevance for the speed and cost of the decision-making process. The LCA results of the production stage of the optimized components showed that the largest contributors to the potential environmental impact of the manufacturing system are the motors due to their material composition, number and mass. The use stage was subsequently recognized as the dominant life cycle stage with Global Warming Potential (GWP) as the leading indicator, due to the long service life (20 years) and the corresponding energy consumption. The analysis of a produced glass bottle’s GWP showed that it was reduced by about 40% through optimizing the production system. The LCC showed that the modernization pays off after about five years of service life and that the decision for making an Investment should not only be based on the required capital expenditure (CAPEX). Rather, operation expenditure (OPEX) should also be considered in order to reflect the savings gained from lower operating costs, which compensate relatively quickly any higher initial expenditure or initial investment. In order to apply Life Cycle Assessment on larger-scale industrial systems, smart and pragmatic LCA modeling approaches have to be developed and adopted, balancing accuracy of results against efficiency in achieving them. An adequate ecological-and-economic assessment tool would reduce the time and effort when making decisions in this context.
Combining eco-efficiency and eco-effectiveness for continuous loop beverage packaging systems: learnings from the Carlsberg Circular Community

Eco-efficiency (i.e., increasing value while reducing resource use and pollution) can with advantage be combined with eco-effectiveness (i.e., maximizing the benefits to ecological and economical systems) to address the challenges posed by the circular economy in the design of circular industrial systems. We present a framework combining life cycle assessment (LCA) and the Cradle to Cradle® (C2C) certification program for the development of continuous loop packaging systems, which was conceived for aluminum cans in the context of the Carlsberg Circular Community. As a first step, the
environmentally optimal beverage packaging life cycle scenario is identified, both in terms of defined use and reuse. Second, the limiting factors are identified for the continuous use of materials in multiple loops, meeting the two requirements in the C2C certification process that address the material level (i.e., “material health” and “material reutilization” criteria) and the “renewable energy” criterion. Then, alternative scenarios are built to meet C2C certification criteria, and LCA is used to quantify the environmental impacts of the resulting improvement strategies, for example, change in material composition, in order to guide the identification of the optimal scenario from an eco-efficiency point of view. Finally, the business perspective is addressed by assessing the potential for a green value network business model for a closed-loop supply. The outcome is a list of prioritized actions needed to implement the most efficient and effective “upcycling” strategy for the beverage packaging, both from an environmental and an economic point of view. In the case of the aluminum cans, the main recommendation from both the LCA and C2C perspective is to ensure a system that enables can-to-can recycling.

Combining or Separating Forward and Reverse Logistics

Purpose – While forward logistics handles and manages the flow of goods downstream in the supply chain from suppliers to customers, reverse logistics (RL) manages the flow of returned goods upstream. A firm can combine reverse logistics with forward logistics, keep the flows separated, or choose a position between the two extremes. The purpose of this paper is to identify the contextual factors that determine the most advantageous position, which the paper refers to as the most advantageous degree of combination.

Design/methodology/approach– The paper first develops a scale ranging from 0% combination to 100% combination (i.e. full separation). Second, using contingency theory the paper identifies the contextual factors described in RL-literature that determine the most advantageous degree of combination. The set of factors is subsequently tested using a case study, which applies a triangulation approach that combines a qualitative and a quantitative method.

Findings – Results show six distinct contextual factors that determine the most advantageous degree of combination. Examples of factors are technical product complexity, product portfolio variation, and the loss of product value over time.

Practical implications – For practitioners the scale of possible positions and set of contextual factors constitute a decision making framework. Using the framework practitioners can determine the most advantageous position of the scale for their firm.

Originality/value – Much RL-research addresses intra-RL issues while the relationship between forward and reverse logistics is under-researched. This paper contributes to RL-theory by identifying the contextual factors that determine the most advantageous relationship between forward and reverse logistics, and proposes a novel decision making framework for practitioners.

Communities of practices as means to develop creativity at work

To cope with the frequent changes healthcare professionals must be creative. A Community of Practice (CoP) is a relational work community based on voluntary participation by practitioners of a particular work (e.g. intensive care unit nursing or maintenance of machine X) that interact and improve their practice. CoPs are known for inducing a propensity to develop knowledge and foster creativity as practitioners interact and build relations, share ideas and discuss experiences. Communities of Practice are often developed as a part of knowledge management initiatives. However, knowledge about how to develop CoPs is still incomplete. This paper reports on an intervention study that contributes to the CoP field through the design and test of a method for CoP development within operations. The study contributes with knowledge about the design of a CoP start-up process and about connecting the CoP with the organization. We propose a method to develop CoP and the method is tested in a blood analysis unit at 'Nordsjællands Hospital' in Denmark and the effect on creativity is evaluated. In order to develop the CoP the following interventions took place: The manager was introduced to CoP theory. The practice was operationalized narrowly as employees performing a specific operational task frequently and experiencing recurring problems. A voluntary CoP facilitator was identified and introduced to CoP theory. She then invited her colleagues to participate in the CoP. The facilitator arranged the start-up workshop where CoP participants were introduced to the timeline, the purpose of the CoP and templates to support collaboration. The facilitator arranged the following CoP meetings.

Company-University Collaboration Types As A Determinant For Knowledge Transfer
This paper develops a framework for a novel measurement of outcomes of different types of company-university collaboration. We test whether the level of formalization and the type of interaction influence the outcomes, in particular knowledge transfer. We extend the existing research by applying novel statistical computational methods from the field of natural language processing to identify the knowledge transfer. We investigate how the level of formalization of collaboration affects the knowledge transfer between universities and companies. Preliminary results indicate that we are able to identify additional forms of knowledge transfer and give companies insights into their potential benefits from different types of relationships. We propose a new perspective that enables companies to shape and adapt their external knowledge search as effective as possible.

Comparing three methods for participatory simulation of hospital work systems
Summative Statement: This study compared three participatory simulation methods using different simulation objects: Low resolution table-top setup using Lego figures, full scale mock-ups, and blueprints using Lego figures. It was concluded the three objects by differences in fidelity and affordance addressed different elements of a hospital work system.

Problem statement: Different methods for simulating the future work system for healthcare professionals have been applied in a number of green field and renovation design projects of hospitals in Denmark. The methods differed in the type of simulation objects representing the work system. Hence, this was an opportunity to study if these differences influenced which elements of a work system were in focus when healthcare professionals simulated and evaluated future work. Preliminary observations indicated this was the case but it was not understood how and why this influence took place.

Research Objective / Question: How does the simulation object influence which elements of a work system are being evaluated in participatory simulation events?
Methodology: Observation notes and video recordings of three types of simulation events using different objects were
analyzed in respect to which elements of a work system were being targeted. A work system was defined as consisting of human work practices embedded in the three interdependent dimensions: space, organization and technology. All simulation events were based on participants playing clinical scenarios using the objects.

Results: Full scale mock-ups significantly addressed the local space and technology/tool elements of a work system. In contrast, the table-top simulation object addressed the organizational issues of the future work system. The blueprint based simulation addressed the organizational issues in combination with a global space outlook, e.g. the layout of an entire department.

Discussion: It is proposed that the simulation objects influence on work system focus is based on two attributes: Fidelity and affordance. Fidelity concerns the degree of resolution or the level of detail of what are being manifested by the simulation object. The affordance is a property of the object concerning how simulation participants will perceive how it may be used. When having a low-resolution model of a work system as in the table-top setup it is much easier to test a number of ‘what if’ scenarios on how to organize the work in different spatial layouts. In addition to the object attributes other factors may play a role in what work system elements are being addressed. An important one seems to be at which point in the hospital design process the simulation is carried out.

Conclusions: Different simulation objects may to a certain degree influence what part of a work system is being addressed in participatory simulation events. For human factors practitioners in hospital design projects it is important to pay attention to this when planning and facilitating simulation events to evaluate different designs.

Comparison between young male drivers' self-assessed and objectively measured driving skills
Self-assessment of skills is a self-generated feedback process that contributes to confidence in one's skills. The higher one's self-assessed skills, the more likely one is to feel competent a particular domain thereby influencing the related behaviors. Drivers' self-assessed driving skills are not always accurate, which may cause serious problems such as underestimation of risk, reckless driving and accidents. Most previous research on self-assessment of driving skills did not compare self-reported skills to objectively measured driving skills, so the aim of this study was to test the accuracy of young male drivers' self-assessments of driving skills using a driving simulator, and to examine whether self-assessment accuracy varied with driving skill, experience or sensation-seeking propensity. Results showed that the drivers' self-assessments were inconsistent with their driving performance, and this inconsistency varied with driving skill, driving experience and sensation-seeking propensity in a safety-critical way.

Comparison of the impacts of urban development and climate change on exposing European cities to pluvial flooding

The economic and human consequences of extreme precipitation and the related flooding of urban areas have increased rapidly over the past decades. Some of the key factors that affect the risks to urban areas include climate change, the densification of assets within cities and the general expansion of urban areas. In this paper, we examine and compare quantitatively the impact of climate change and recent urban development patterns on the exposure of four European cities to pluvial flooding. In particular, we investigate the degree to which pluvial floods of varying severity and in different geographical locations are influenced to the same extent by changes in urban land cover and climate change. We have selected the European cities of Odense, Vienna, Strasbourg and Nice for analyses to represent different climatic conditions, trends in urban development and topographical characteristics. We develop and apply a combined remote-sensing and flood-modelling approach to simulate the extent of pluvial flooding for a range of extreme precipitation events for historical (1984) and present-day (2014) urban land cover and for two climate-change scenarios (i.e. representative concentration pathways, RCP 4.5 and RCP 8.5). Changes in urban land cover are estimated using Landsat satellite imagery for the period 1984-2014. We combine the remote-sensing analyses with regionally downscaled estimates of precipitation extremes of current and expected future climate to enable 2-D overland flow simulations and flood-hazard assessments. The individual and combined impacts of urban development and climate change are quantified by examining the variations in flooding between the different simulations along with the corresponding uncertainties. In addition, two different assumptions are examined with regards to the development of the capacity of the urban drainage system in response to urban development and climate change. In the "stationary" approach, the capacity resembles present-day design, while it is updated in the "evolutionary" approach to correspond to changes in imperviousness and precipitation intensities due to urban development and climate change respectively. For all four cities, we find an increase in flood exposure corresponding to an observed absolute growth in impervious surfaces of 7-12% during the past 30 years of urban development. Similarly, we find that climate change increases exposure to pluvial flooding under both the RCP 4.5 and RCP 8.5 scenarios. The relative importance of urban development and climate change on flood exposure varies considerably between the cities. For Odense, the impact of urban development is comparable to that of climate change under an RCP 8.5 scenario (2081-2100), while for Vienna and Strasbourg it is comparable to the impacts of an RCP 4.5 scenario. For Nice, climate change dominates urban development as the primary driver of changes in exposure to flooding. The variation between geographical locations is caused by differences in soil infiltration properties, historical trends in urban development and the projected regional impacts of climate change on extreme precipitation. Developing the capacity of the urban drainage system in relation to urban development is found to be an effective adaptation measure as it fully compensates for the increase in runoff caused by additional sealed surfaces. On the other hand, updating the drainage system according to changes in precipitation intensities caused by climate change only marginally reduces flooding for the most extreme events.

We present a solution method for the liner shipping network design problem which is a core strategic planning problem faced by container carriers. We propose the first practical algorithm which explicitly handles transshipment time limits for all demands. Individual sailing speeds at each service leg are used to balance sailing speed against operational costs, hence ensuring that the found network is competitive on both transit time and cost. We present a matheuristic for the problem where a MIP is used to select which ports should be inserted or removed on a route. Computational results are presented showing very promising results for realistic global liner shipping networks. Due to a number of algorithmic enhancements, the obtained solutions can be found within the same time frame as used by previous algorithms not handling time constraints. Furthermore, we present a sensitivity analysis on fluctuations in bunker price which confirms the
applicability of the algorithm.

Complexity of Configurators Relative to Integrations and Field of Application

Configurators are applied widely to automate the specification processes at companies. The literature describes the industrial application of configurators supporting both sales and engineering processes, where configurators supporting the engineering processes are described more challenging. Moreover, configurators are commonly integrated to various IT systems within companies. The complexity of configurators is an important factor when it comes to performance, development and maintenance of the systems. A direct comparison of the complexity based on the different application and IT integrations is not addressed to a great extent in the literature. Thus, this paper aims to analyse the relationship of the complexity of the configurators, which is based on parameters (rules and attributes), in terms of first different applications of configurators (sales and engineering), and second integrations to other IT systems. The research method adopted in the paper is based on a survey followed with interviews where the unit of analysis is based on operating configurators within a company.

Comprehensive Assessment of Human Health Impacts and Benefits of Fruits and Vegetables in a LCA Context

Nutritional effects from the ‘use stage’ of the life cycle of food products can have a substantial effect on human health; yet, they are often not considered in life cycle assessment (LCA). In this study we explore the trade-offs between environmental and nutritional health effects associated with increased consumption of fruits and vegetables in the US diet. We employ the Combined Nutritional and Environmental Life Cycle Assessment (CONE-LCA) framework that compares environmental and nutritional effects of foods in a common endpoint metric, Disability Adjusted Life Years (DALY). Starting from one serving of 161 g fruits and 123 g vegetables as functional unit (FU), associated life cycle emissions, e.g. greenhouse gases and particulate matter (PM) precursors, and intake of pesticide residues in food are linked to health impacts in DALY/FU. Global warming and PM human health impacts are assessed following a traditional LCA approach. For PM, we couple emissions with an epidemiology-based dose-response to estimate impacts. For pesticide residues exposure, we use publicly available health impacts derived by combining exposure modelling of pesticide residue with toxicological studies for numerous pesticide active ingredients. The nutritional assessment is based on effect factors estimated using the 2010 health burden attributable to corresponding dietary risk factors in DALY from the global burden of disease (GBD) and daily consumption food consumption based on the National Health and Nutrition Examination Survey (NHANES) 2009-2012. One serving of fruits and vegetables (Figure 1), 40% due to NH3 as PM precursor, corresponding to 0.08 μg DALY, (0.03 μg DALY/serving). From a nutritional perspective, adding one serving of fruits to the average US diet could result in an avoided health impact of 19.0 μg DALY (respective avoided impact for vegetables: 5.25 μg DALY). Overall, adding one serving of fruits to the average US diet may lead to substantial health benefits: nutrition-related avoided impact (benefit) is 50 times higher than environmental health impacts (Figure 2). The benefit is slightly enhanced when increased fruit intake is substituted by food associated with adverse health outcomes, such as trans-fat and red meat, with the benefit mainly linked to avoided nutritional health impact. Benefits exceed impacts even when considering an uncertainty factor of 400 for the impacts due to pesticide residues for the increased fruit consumption scenario but not for the increased vegetable consumption scenario. THE CONE-LCA framework enables the comparison of environmental and nutritional impacts and benefits of food items on human health using a common metric. The preliminary results of this case study indicate the importance of considering nutritional effects in food-LCA and suggest that nutritional health effects of food
items, and specifically of fruits and vegetables, can be substantial compared to environmental impacts. This approach could be extended to other human health impacts (e.g. water use) and used in making sustainable diets decisions.

Computing interval-valued reliability measures: application of optimal control methods

The paper describes an approach to deriving interval-valued reliability measures given partial statistical information on the occurrence of failures. We apply methods of optimal control theory, in particular, Pontryagin’s principle of maximum to solve the non-linear optimisation problem and derive the probabilistic interval-valued quantities of interest. It is proven that the optimisation problem can be translated into another problem statement that can be solved on the class of piecewise continuous probability density functions (pdfs). This class often consists of piecewise exponential pdfs which appear as soon as among the constraints there are bounds on a failure rate of a component under consideration. Finding the number of switching points of the piecewise continuous pdfs and their values becomes the focus of the approach described in the paper. Examples are provided.

**Conceptual Modelling for Product Configuration Systems**

Individual customization of goods and processes in different industries leads to complexity due to a growing mix of products both regarding characteristics of products and support services. In order to eliminate complexity and challenges in product/process customizing, smart IT systems called Product Configuration Systems (PCS), have been proposed as the solution both by researchers and practitioners and various benefits are mentioned from utilizing PCSs. Based on the latest literature, there are challenges reported in all phases of PCS projects including planning, development, and documentation. Moreover, the challenges become more serious when it involves complicated products/processes in engineer-to-order (ETO) companies. The purpose of this thesis is to contribute to the existing knowledge of managing PCS projects by proposing frameworks and tools to address some of the main challenges.

First, this research focuses on the reported benefits and challenges in different phases of PCS projects aligned with the gaps in the current literature. Second, the study presents a survey in order to have a comprehensive overview to assess the most important challenges in the area. Third, in order to overcome different challenges in the PCS projects, the study contributes to the literature in forms of different frameworks, tools, and IT solutions. Addressing the defined challenges, the following frameworks are proposed. 1) A framework is provided for business cases in PCS projects in order to estimate the needed investments and financial return-on-investment. 2) Furthermore, the research proposes a framework and different tools to scope the whole PCS project from planning to the maintenance phase. 3) Afterwards, the study suggests a framework to manage the knowledge in PCS projects due to reported challenges. 4) In order to make it possible to model, maintain, communicate, and document complicated products/process, a framework aligned with an IT tool is developed in close collaboration with industry. 5) Finally, the study contributes to the direction of integration of PCS and other IT systems by showing the automation impact of this alignment.

The tools and frameworks developed have been evaluated based on existing literature and by empirical tests in companies. Furthermore, areas for further investigation have been identified.
Connecting strategy and execution in global R&D
The paper investigates the relationship between global product development strategic decisions, which include outsourcing, offshoring practices as well as strategic alliances, and their impact on the day-to-day business in a global and open innovation context. By adopting an exploratory inductive research, founded on core literature in the area and using empirical data from four companies in different industries, the study intends to understand the interconnection between the shift toward a global R&D strategy, and the dependent changes at the operational and managerial level. The series of changes in the innovation network are strictly connected with the company's source of competitive advantage, their internationalisation drivers, the internationalisation practices adopted, and the series of organisational capabilities needed to support the internationalization as well as externalization of innovation sources. Topics: Design organisation and management, Design to advance resource-limited societies, Design research applications and case studies, Design to embrace resource limitations

Considering passenger and operator inconvenience in the scheduling of large railway projects
The continued development and renewal of railway infrastructure and technology is necessary to enable railway operators to provide high quality services subject to ever increasing demand. However, the execution of large infrastructure projects causes disturbances in the network due to the occupation of infrastructure over extended periods of time. In this paper we propose a multiobjective project scheduling optimization model for railway infrastructure projects that takes inconvenience caused to users of the infrastructure into account. We illustrate how the model can be used in an interactive way by planners based on their preferences, and we show that Pareto optimal solutions can be found in reasonable time using instances with realistic features. The result is a decision support model to aid infrastructure project planners in ensuring that passenger and operator inconvenience are also taken into account.
Consistent cost curves for identification of optimal energy savings across industry and residential sectors

Energy savings are a key element in reaching ambitious climate targets and may contribute to increased productivity as well. For identification of the most attractive saving options cost curves for savings are constructed illustrating potentials of savings with associated costs. In optimisation modelling these cost options are then compared with the cost of producing energy and all savings with negative costs and cost below the cost of producing the energy including the associated externality costs are expected to be implemented. There are however several methodological issues associated with constructing and applying the cost curves in modelling: • Cost curves do not have the same cost interpretation across economic subsectors and end-use technologies (investment cost for equipment varies – including/excluding installation – adaptation costs – indirect production costs) • The time issue of when the costs are incurred and savings (difference in discount rates both private and social) • The issue of marginal investment in a case of replacement anyway or a full
investment in the energy saving technology • Implementation costs (and probability of investment) differs across sectors • Cost saving options are not additive - meaning that marginal energy savings from one option depends on what other options implemented We address the importance of these issues and illustrate with Danish cases how large the difference in savings cost curves can be if different methodologies are used. For example, the difference between marginal investment costs in residential heating of a more efficient building element (windows) in a larger renovation project compared to the costs of just replacing the windows. This is done based on some of the results from Zvingilaite & Klinge Jacobsen 2016. We compare to the results found for residential savings in Giraudet et. al. 2012 and Amstalden et. al. 2007. For our case the resulting savings potential below a given level of costs can be up to a factor of 5 times larger if only the marginal cost measure is used. For national energy plan strategies this results in much more emphasis on energy savings, than renewable energy expansion as a way to achieve fossil fuel reductions if it is possible to implement all heating savings with their marginal costs. As saving potentials are not additive for savings in a specific end-use entity it is difficult to compare savings in one sector comprising many options together and single options in another sector. We illustrate that a saving option in one sector (eg a more efficient pump) would be difficult to compare with the savings from replacing an entire production line in a factory with a more efficient one. If the average cost of the two are compared then probably the efficient pump would be preferred due to low costs compared to the full production line. This would leave out the elements of the production line where independent savings investments might have cost that are just as low as for the pump. We argue that comparing across sectors should be carried out with similar sets of savings options (small individual replacements in each sector, and comparable larger technology switches in each sector).

Constraints and Creativity in NPD - Testing the Impact of 'Late Constraints'
The aim of the presented work is to investigate how the timing of project constraints can influence the creativity of the output in New Product Development (NPD) projects. When seeking to produce a creative output, is it beneficial to know all constraints when initiating a project, or will constraints introduced throughout a project potentially lead to a more creative output? While the relationship between constraints and creativity is fairly well studied, the question of how introducing constraints late in a project can influence creativity is still unanswered. A single factor, two level experiment was conducted, involving 12 teams of industrial designers from three different countries, each team working on two 30 minutes design tasks. In one condition all constraints were given at the start, and in the other one new radical constraint was added after 12 minutes. The output from all 24 tasks was assessed for creativity using the Consensual Assessment Technique (CAT), and a comparative within-subjects analysis found no significant different between the two conditions. Controlling for task and assessor a small but non-significant effect was found, in favor of the ‘late constraint’ condition. Thus, in the presented setup no negative impact of adding radically new constraints during a project was found, highlighting for managers that it is not crucial to a project’s creative output to have all constraints from the beginning.

The proliferation of increasingly energy-efficient (EE) appliances is a key strategy to address the impacts of rising residential electricity demand (Danish Energy Agency 2017). To this end, governments and institutions are interested in understanding the drivers of consumer choice between conventional and environmentally friendly alternatives when
purchasing new household electric appliances. This study employs empirical data from a survey conducted by the Danish Energy Agency to model the decision criteria behind Danish consumer investment in energy-efficient labeled appliances. The analysis uses logistic regression over a set of socioeconomic, demographic, and behavioral variables to predict purchase propensities. The findings are relevant for policy makers interested in targeting consumers in the appliance market, particularly for a relatively wealthy national context. The study concludes by integrating the predicted propensities with an energy-systems model to assess the nation-wide impact of efficient appliances' uptake in terms of electricity, emissions and economic savings.

**Container shipping service selection and cargo routing with transshipment limits**
We address the tactical planning problem faced by container liner shipping companies to select a set of sailing services from a given pool of candidate services and route available cargo over the chosen services so as to maximize profit. One of the distinctive features of our model is that it incorporates limits on the number of transshipments for each container, a common service requirement in practice. These limits can vary by shipment attributes such as origin and destination, and cargo priority. We propose a new stage-indexed multi-commodity flow model that is based on an augmented network containing links (representing sub-paths) between every pair of ports visited by a candidate service. This sub-path structure, together with our approach of indexing the flow variables by transportation stage, enables the model to accurately capture transshipment costs and enforce transshipment limits. To reduce the computational time to solve this problem, we develop preprocessing steps that exploit network structure to eliminate variables, describe valid inequalities to strengthen the model's linear programming relaxation, and propose an optimization-based heuristic algorithm to generate good initial solutions. We report successful computational results for realistic problem instances from a benchmark suite of liner shipping problems, solved using a standard solver applied to our reduced and strengthened model.

Contribution of organic farming to public goods in Denmark

The potential contribution of organic farming to the public goods, 'Nature and Biodiversity', 'Environment', 'Energy and Climate', 'Human Health and Welfare' and 'Animal Health and Welfare' in Denmark is guided and partly secured by the principles and specific requirements of the EU Organic Regulation. However, other factors, such as the production type, farm size, geographical location and—not the least—the management of the farm, also influence the contribution. Using the ban on synthetic pesticides and restricted use of antibiotics, including the requirements to compensate for and prevent such uses in organic farming, as examples, the positive and negative contributions of organic farming in relation to selected public goods were analysed. The contributions of organic farming to Nature and Biodiversity and Human and Animal Health and Welfare are mainly positive compared to conventional farming for all farm types, whilst the effects on Environment and Energy and Climate are mixed; i.e. some effects are positive and others are negative. The analysis revealed a need for further documentation and revision of the organic principles and specific organic requirements in particular in relation to the public goods Energy and Climate, which at present are not
addressed in the EU Organic Regulation. Moreover, some organic farming requirements and practices cause dilemmas; e.g. more space per animal and outdoor access improves Animal Health and Welfare but at the same time has negative effects on Environment, Energy Consumption and Climate Change. These dilemmas should be solved before OA may be fully attractive as an integrated policy measure supporting jointly several public goods objectives.

**Contributions of Local Farming to Urban Sustainability in the Northeast United States**

Food consumption is an important contributor to a city’s environmental impacts (carbon emissions, land occupation, water use, etc.) Urban farming (UF) has been advocated as a means to increase urban sustainability by reducing food-related transport and tapping into local resources. Taking Boston as an illustrative Northeast U.S. city, we developed a novel method to estimate sub-urban, food-borne carbon and land footprints using multiregioninput-output modeling and nutritional surveys. Computer simulations utilizing primary data explored UF’s ability to reduce these footprints using select farming technologies, building on previous city-scale UF assessments which have hitherto been dependent on proxy data for UF. We found that UF generated meagre food-related carbon footprint reductions (1.1–2.9% of baseline 2211 kg CO2 equivalents/capita/annum) and land occupation increases (<1% of baseline 9000 m² land occupation/capita/annum) under optimal production scenarios, informing future evidence-based urban design and policy crafting in the region. Notwithstanding UF’s marginal environmental gains, UF could help Boston meet national nutritional guidelines for vegetable intake, generate an estimated $160 million U.S. in revenue to growers and act as a pedagogical and community building tool, though these benefits would hinge on large-scale UF proliferation, likely undergirded by environmental remediation of marginal lands in the city.

Cost-competitiveness of organic photovoltaics for electricity self-consumption at residential buildings: A comparative study of Denmark and Greece under real market conditions

To address sustainability challenges, photovoltaics (PV) are regarded as a promising renewable energy technology. Decreasing PV module costs and increasing residential electricity prices have made self-consumption of PV-generated electricity financially more attractive than exporting to the grid. Organic photovoltaics (OPV) are an emerging thin-film PV technology that shows promise of greatly improving the environmental and economic performances of PV technologies. Previous studies have estimated the current and future costs of OPV technologies, but the attractiveness of investing in OPV systems has not been evaluated under real market conditions, especially under PV self-consumption schemes. In this study, we investigate the self-consumption of electricity generation from conventional and organic PV systems installed at residential houses in two different countries, Denmark and Greece, under current PV regulatory frameworks. We then focus on modelling and assessing the cost-competitiveness of organic PV technologies based on cost estimations for existing pilot-scale (kW-range), and projected scale-up (100MW) and industrial-scale (100GW) manufacturing capacity levels. Our generic results applying to all PV technologies show that PV systems installed at residential houses in Greece perform economically better than those in Denmark do in terms of self-sufficiency and gross electricity bill savings (i.e. excluding PV costs). Using the two country cases, which present very different settings, we characterise and discuss the influence of three key parameters of the economic performance of PV systems, namely the PV regulatory scheme, the solar irradiation level and the temporal match between the electricity consumption and solar irradiation profiles. Focusing on organic PV systems developed in an industrial-scale cost setting (1.53€/Wp), we find that they deliver significant electricity bill savings for residential houses in Greece (38%) under current conditions, while they may not be sufficiently attractive for residential houses in Denmark (6.5%) due to mainly the different PV regulatory schemes. Based on these findings, we therefore recommend investors interested in renewable energy technologies to pursue scaling up the manufacturing capacity of OPV technologies, as well as assess a large number of countries to identify and prioritise financially attractive settings for PV self-consumption.

Cradle to Cradle and LCA
Cradle to Cradle (C2C) offers a positive vision of a future, where products are radically redesigned to be beneficial to humans and the environment. The idea is not to reduce negative impacts (as in LCA), but to increase positive impacts. This chapter presents the C2C concept and its relationship with the circular economy, the C2C certification and examples of C2C certified or inspired products and systems. This is followed by a comparison of C2C with eco-efficiency and LCA. Because of their important differences, we conclude that care should be taken when combing C2C and LCA, e.g. using LCA to evaluate products inspired by C2C. We then provide an in-depth analysis of the conflicts between C2C and LCA and offer solutions. Finally, we reflect upon how LCA practitioners can learn from C2C in terms of providing a vision of a sustainable future, creating a sense of urgency for change and communicating results in an inspiring way.

Creating Evaluation Profiles for Games Designed to be Fun: An Interpretive Framework for Serious Game Mechanics
Background. Games can be great pedagogical tools for educators and students. COTS games (commercial-off-the-shelf) are designed for the pure purpose of leisure but can also contain educational value. Aim. In this paper, we address the potential of COTS games as serious games. We develop an interpretive evaluation framework that can identify the educational value in COTS games.
Application. The presented framework can create evaluative profiles of the learning, social, game, and immersive mechanics of COTS games as educational tools. Moreover, the framework can position COTS games between four intertwined dimensions, namely pedagogical, design, knowledge, and sociotechnical considerations. Demonstration. To validate the practical application of the interpretive framework, we apply it to a real-world example. Our demonstration reveals the usefulness of the framework. Conclusions. The framework enables critical reflection on the game mechanics; thereby capturing the complexity of the game mechanics that makes COTS game both educational and fun to play.
Critical Review
Manipulation and mistakes in LCA studies are as old as the tool itself, and so is its critical review. Besides preventing misuse and unsupported claims, critical review may also help identifying mistakes and more justifiable assumptions as well as generally improve the quality of a study. It thus supports the robustness of an LCA and increases trust in its results and conclusions. The focus of this chapter is on understanding what a critical review is, how the international standards define it, what its main elements are, and what reviewer qualifications are required. It is not the objective of this chapter to learn how to conduct a critical review, neither from a reviewer nor from a practitioner perspective. The foundation of this chapter and the basis for any critical review of LCA studies are the International Standards ISO 14040:2006, ISO 14044:2006 and ISO TS 14071:2014.

Data-driven engineering design research: Opportunities using open data

Engineering Design research relies on quantitative and qualitative data to describe design-related phenomena and prescribe improvements for design practice. Given data availability, privacy requirements and other constraints, most empirical data used in Engineering Design research can be described as “closed”. Keeping such data closed is in many cases necessary and justifiable. However, this closedness also hinders replicability, and thus, may limit our possibilities to test the validity and reliability of research results in the field. This paper discusses implications and applications of using the already available and continuously growing body of open data sources to create opportunities for research in Engineering Design. Insights are illustrated by an examination of two examples: a study of open source software repositories and an analysis of open business registries in the cleantech industry. We conclude with a discussion about the limitations, challenges and risks of using open data in Engineering Design research and practice.

Defining specific problems in the Thai government hospital buildings. A study of architectural planning and space management of Maharaj hospital, Chiang Mai Thailand

The purpose of this paper is to present and analyse the preliminary results of field work observation in one of the biggest government hospitals in Thailand – the Maharaj Hospital, Chiang Mai, Thailand. Hospitals in Thailand are the result of the imported concept from the European and American hospitals. The ideas of hospital architecture from Western countries have been adopted since nineteenth century until the contemporary period. Many of the Thai government hospitals constructed between 1960s and 1970s are still in use. The government hospitals are expanding (incremental development) without considering long term effects in the hospital planning. Therefore, this study investigated what are the factors that cause the incremental development of medical buildings in the Thai government hospitals. Moreover, this study investigated the current situations in a Thai government hospital (Maharaj hospital) where the hospital spatial arrangement is effected by the incremental development. The methodology of this study is done by reviewing literature of the Thai hospital landscape, building assessment tools such as Usability, Space management, and USEtool concepts.

Later, an empirical survey (walk-through observations) is conducted to explore daily situations in the Maharaj Government hospital where the hospital is facing the incremental development. Data was collected by documentation such as architectural drawings and photographs and architectural plan analysis was implemented to analyse the spatial arrangement of the Maharaj Hospital planning and identify problems caused by the incremental development. This paper synthesizes the findings from literature review of the Thai healthcare context and a walk-through observation in Maharaj hospital. According to the review of the Thai healthcare general context, there are three main factors that cause the incremental development of the hospital buildings (1) the lack of local general practitioners and poor services of primary care offered by community healthcare centers (2) limited number of government hospital (3) the implementation of Thailand’s universal coverage scheme. These three factors resulted in an easy access to government hospitals and dramatically increase of patient number. Therefore, hospitals need to expand to enable sufficient services for the high number of patients. Walk-through observations identify and emphasis the effects caused by the incremental development of hospital buildings. The results from empirical survey show that confusion of way-finding and the overlapping between waiting areas and non-clinical areas are the problems caused by the incremental development. The problems caused by incremental development was created by two factors (1) the lack of planning in hospital architecture (2) the lack of integration of the Thai culture in hospital design.

Delay estimation on a railway-line with smart use of micro-simulation

This paper formulates a delay propagation model that estimates total railway line delay as a polynomial function of a single primary delay. The estimate is derived from a finite series of delays over a horizon that spans two dimensions: the length
of the railway line and the number of trains in the service plan. The paper shows that the total delay estimate is a cubic relation for small primary delays.

A probabilistic approach is presented to combine the total delay functions of primary delays given to different trains. The final estimate is the total delay on railway lines, after a random incident has occurred. The model can be integrated in railway timetable analysis to reduce the number of necessary simulations, and can be used when the computation speed is an issue, such as on-line rescheduling algorithms. The model is demonstrated with an analysis of a Danish suburban railway.

Designers' identity: Development of personal attributes and design skills over education
Designers' Professional identity (DPI) is a social- and self-perceptive construct through which designers are able to identify themselves. To understand the development of DPI, not just as a profession but also as an educational process, there is a need to consider the designer as both individual and trained professional. These interactions become also a necessary foundation for professionalism that is especially important for design activity. For this study, a psychometric survey was developed by taking in consideration both aspects of DPI, making use of a set of elements distilled from literature as conceptual parameters for Personal Attributes and Design Skills. The survey evaluated professional self-awareness of design students at bachelor and master level; also providing a first profile model of the two groups. The dynamics of the relations between the DPI elements changes and develops very slowly due to the process of identity consolidation over the educational period. Further, DPI consolidates through a lifelong learning process. These results provide an initial insight into the development of DPI and the challenges of measuring this subjective aspect over education.

Design of grid tariffs in electricity systems with variable renewable energy and power to heat
Large shares of variable renewable energy (VRE), requires flexibility solutions are developed. Considerable flexibility potentials exist from large consumers, e.g. power-to-heat (P2H) in district heating (DH). However, the existing grid tariffs obliterate the price signals from the wholesale electricity market and diminish the business cases for these technologies by increasing the costs of their electricity consumption. With the present tariff structure, only a very small part of the flexibility potential is deployed or operated flexible. In this paper we compare two different grid tariff designs that facilitate more flexible energy demand of DH operators. This is illustrated by a case study of Denmark that clearly demonstrates that the introduction of innovative tariffs will improve the business case for flexible P2H technologies and increase the value of VRE. In this way larger flexibility potentials can be induced and larger shares of VRE become integrated in the energy systems.
Developing a model for measuring fear of pain in Norwegian samples: The Fear of Pain Questionnaire Norway

Fear of pain is highly correlated with pain report and physiological measures of arousal when pain is inflicted. The Fear of Pain Questionnaire III (FPQ-III) and the Fear of Pain Questionnaire Short Form (FPQ-SF) are self-report inventories developed for assessment of fear of pain (FOP). A previous study assessed the fit of the FPQ-III and the FPQ-SF in a Norwegian non-clinical sample and proved poor fit of both models. This inspired the idea of testing the possibility of a Norwegian FOP-model. A Norwegian FOP-model was examined by Exploratory Factor Analysis (EFA) in a sample of 1112 healthy volunteers. Then, the model fit of the FPQ-III, FPQ-SF and the Norwegian FOP-model (FPQ-NOR) were compared by Confirmatory Factor Analysis (CFA). Sex neutrality was explored by examining model fit, validity and reliability of the 3 models amongst male and female subgroups. The EFA suggested either a 4-, a 5- or a 6-factor Norwegian FOP model. The eigenvalue criterion supported the suggested 6-factor model, which also explained most of the variance and was most interpretable. A CFA confirmed that the 6-factor model was better than the two 4- and 5-factor models. Furthermore, the CFA used to test the fit of the FPQ-NOR, the FPQ-III and the FPQ-SF showed that the FPQ-NOR had the best fit of the 3 models, both in the whole sample and in sex sub-groups. A 6-factor model for explaining and measuring FOP in Norwegian samples was identified and termed the FPQ-NOR. This new model constituted six factors and 27 items, conceptualized as Minor, Severe, Injection, Fracture, Dental, and Cut Pain. The FPQ-NOR had the best fit overall and in male- and female subgroups, probably due to cross-cultural differences in FOP. This study highlights the importance on exploratory analysis of FOP-instruments when applied to different countries or cultures. As the FPQ-III is widely used in both research and clinical settings, it is important to ensure that the models construct validity is high. Country specific validation of FOP in both clinical and non-clinical samples is recommended.
Developing communities of practice in health care

Purpose
Standard operating procedures (SOPs) are a part of healthcare operations but relying on explicit knowledge is not necessarily sufficient to continuously adapt and improve processes. The theory of communities of practice (CoP) proposes an approach to knowledge sharing that could supplement the use of SOPs. A CoP is a social community formed around a practice (e.g. ICU nursing) which induce a propensity to share experiences and thereby constitute knowledge sharing (Lave & Wenger 1991; Brown & Duguid 1991).

CoP was conceived as a descriptive construct but has gained popularity and is found to improve practice performance, but knowledge about developing and measuring CoP is lacking (Ison et al. 2014).

We propose a method to develop a CoP and the method is tested in a blood analysis unit at 'Nordsjælland Hospital' in Denmark.

Design/methodology/approach
The interventions were identified from current CoP research. Interventions were initiated just after baseline measurement. The following interventions took place: The practice was operationalized narrowly as employees performing a specific operational task. The practice was chosen due to a high frequency and recurring problems. A voluntary CoP coordinator was identified. She then invited her colleagues to participate in the CoP and arranged CoP meetings.

The 'Event Effect Method' was used to control for effect modifiers by identifying events both part and not part of the intervention and estimating their effect on CoP.

Originality/value
The development method improved knowledge sharing and the SOP. The method confirmed some earlier findings regarding CoP development and raises new questions regarding participant engagement, researcher role and start-up workshop.

Practical implications
The results indicate that knowledge sharing within operations can be improved by considering tacit and explicit knowledge sharing as supplementary.

**Development of a generalized integral jet model**

Integral type models to describe stationary plumes and jets in cross-flows (wind) have been developed since about 1970. These models are widely used for risk analysis, to describe the consequences of many different scenarios. Alternatively, CFD codes are being applied, but computational requirements still limit the number of scenarios that can be dealt with using CFD only. The integral models, however, are not suited to handle transient releases, such as releases from pressurized equipment, where the initially high release rate decreases rapidly with time. Further, on gas ignition, a second model is needed to describe the rapid combustion of the flammable part of the plume (flash fire) and a third model has to be applied for the remaining jet fire. The objective of this paper is to describe the first steps of the development of an integral-type model describing the transient development and decay of a jet of flammable gas after a release from a pressure container. The intention is to transfer the stationary models to a fully transient model, capable to predict the maximum extension of short-duration, high pressure jets. The model development is supported by conducting a set of transient ignited and unignited spontaneous releases at initial pressures between 25bar and 400bar. These data forms the basis for the presented model development approach.

**Development of Comparative Toxicity Potentials of TiO₂ Nanoparticles for Use in Life Cycle Assessment**

Studies have shown that releases of nanoparticles may take place through the life cycle of products embedding nanomaterials, thus resulting in potential impacts on ecosystems and human health. While several life cycle assessment (LCA) studies have assessed such products, only a few of them have quantitatively addressed the toxic impacts caused by released nanoparticles, thus leading to potential biases in their conclusions. Here, we address this gap and aim to provide a framework for calculating characterization factors or comparative toxicity potentials (CTP) for nanoparticles and derive CTP values for TiO₂ nanoparticles (TiO₂-NP) for use in LCA. We adapted the USEtox 2.0 consensus model to integrate the SimpleBox4Nano fate model, and we populated the resulting model with TiO₂-NP specific data. We thus calculated CTP values for TiO₂ nanoparticles for air, water, and soil emission compartments for freshwater ecotoxicity and human toxicity, both cancer effects and noncancer effects. Our results appeared plausible after benchmarking with CTPs for other nanoparticles and substances present in the USEtox database, while large differences were observed with CTP values for TiO₂ nanoparticles published in earlier studies. Assumptions, which were performed in those previous studies because of lack of data and knowledge at the time they were made, primarily explain such discrepancies. For future assessment of potential toxic impacts of TiO₂ nanoparticles in LCA studies, we therefore recommend the use of our calculated CTP.

Different Styles for Different Needs – The Effect of Cognitive Styles on Idea Generation

Researchers are engaged in finding the precursors for innovation. Drawing on Kirton’s Adaption-Innovation (KAI) Inventory, we explicitly test Kirton’s central premise that cognitive styles differentiate between preferences for producing ideas in a certain way. We argue that the generation of either a magnitude or original ideas is governed by different underlying cognitive styles. In a study with 191 individuals, we find that the cognitive style originality associates with ideational fluency whereas the rule governance style associates with the generation of original ideas. By providing a cognitive explanation for how ideas are generated, we deepen the understanding of the idea generation process. This is particularly important for the future use of the KAI and for organizations that strive to be innovative.

Discrete choice models for commuting interactions
An emerging quantitative spatial economics literature models commuting interactions by a gravity equation that is mathematically equivalent to a multinomial logit model. This model is widely viewed as restrictive because of the independence of irrelevant alternatives (IIA) property that links substitution behavior in response to changes in the
attractiveness of choice alternatives to choice probabilities in a mechanistic way. This is relevant for counterfactual analysis. In this paper we examine the appropriateness of the commuting model from a theoretical as well as an empirical point of view. We show that conventional specification tests of the multinomial logit model are of limited use when alternative specific constants are used, as is common in the recent literature, and offer no information with respect to the validity of IIA. In particular, we show that maximum likelihood estimation of relevant nested logit model is impossible because the crucial parameters are not identified. We discuss cross-nested and mixed logit as alternatives. We argue that a comparison between predicted and actual changes in commuting flows in response to a change in the attractiveness of choice alternatives provides a more informative test for the validity of the multinomial logit model for commuting interaction and report the results of such a test – as well as others – for data referring to Copenhagen.

**Discussions About Lying With An Ethical Reasoning Robot**
The conversational ethical reasoning robot Immanuel is presented. Immanuel is capable of defending multiple ethical views on morally delicate situations. A study was conducted to evaluate the acceptance of Immanuel. The participants had a conversation with the robot on whether lying is permissible in a given situation. The robot first signaled uncertainty about whether lying is right or wrong in the situation, then disagreed with the participant's view, and finally asked for justification. The results indicate that participants with a higher tendency to utilitarian judgments are initially more certain about their view as compared to participants with a higher tendency to deontological judgments. These differences vanish at the end of the dialogue. Lying is defended and argued against by both utilitarian and deontologically oriented participants. The diversity of the reported arguments gives an idea of the variety of human moral judgment. Implications for the design and application of morally competent robots are discussed.

Dynamic Bluetooth Beacons for People with Disabilities

This paper focuses on digital aids for sight impairment and motor disabilities. We propose an Internet of Things (IoT) platform for discovering nearby items, getting their status, and interacting with them by e.g., voice commands or gaze gestures. The technology is based on Bluetooth Low Energy, which is included in consumer electronics such as smartphones without requiring additional hardware. The paper presents a prototype platform illustrated by concepts of use.

Dynamic Heat Production Modeling for Life Cycle Assessment of Insulation in Danish Residential Buildings

Residential building insulation is regarded as an easy solution for environmentally friendly building design. This assumption is based on the perception that the amount of thermal energy used to create insulation in most cases is much smaller than the amount of thermal energy that is needed for space heating without insulation over the lifespan of a building. When the energy sources for insulation production are similar to the energy mix that supplies heat, this logic is valid to very high levels of insulation. However, in Denmark, as well as many other countries, this assumption is becoming increasingly incorrect. Given the generally long service life of buildings, the significance of future energy mixes, which are expected/intended to have a smaller environmental impact, can be great. In this paper, a reference house is used to assess the life cycle environmental impacts of mineral wool insulation in a Danish single-family detached home. This single family house, is based on averages of current Danish construction practices with building heat losses estimated using Be10. To simulate a changing district heating grid mix, heat supply fuel sources are modeled according to Danish energy mix reports of fuel mix since 1972. Both the dynamic impact potentials saved by using insulation and the impacts induced from insulation production are utilized to create an overall dynamic energy inventory for the life cycle assessment. Our study shows that the use of such a dynamic energy inventory is necessary for increasing the validity of optimization assessment, and our study further shows that it is likely that current Danish regulation will not promote optimum levels of insulation in the near future.

Dynamic queuing transmission model for dynamic network loading

This paper presents a new macroscopic multi-class dynamic network loading model called Dynamic Queuing Transmission Model (DQTM). The model utilizes ‘good’ properties of the Dynamic Queuing Model (DQM) and the Link Transmission Model (LTM) by offering a DQM consistent with the kinematic wave theory and allowing for the representation of multiple vehicle classes, queue spillbacks and shock waves. The model assumes that a link is split into a moving part plus a queuing part, and that traffic dynamics are given by a triangular fundamental diagram. A case-study is investigated and the DQTM is compared with single-class LTM, single-class DQM and multi-class DQM. Under the model assumptions, single-class models indicate that the LTM and the DQTM give similar results and that the shock wave property is properly included in the DQTM, while the multi-class models show substantially different travel times for two vehicle classes. Moreover, the results show that the travel time will be underestimated without considering the shock wave property.

Dynamics of Eco-innovation in Emerging Economies: the Case of Green Food Production in Brazil

The growing awareness of the unsustainability of economic growth in the world brings up the necessity of adopting measures to make it more ecologically responsible and sustainable, i.e. more appropriate to social needs and environmental limits of the planet (SACHS, 1993; DALY, H., FARLEY, J., 2003). More recently, the rising environmental concerns are affecting economic activity so significantly that we are referring to a ‘green economy’ (ANDERSEN, 2010). In this paper, we review existing findings and try to present the scenario behind the theme contrasting Brazil with international trends, discuss data availability and formulate research questions and hypothesis. Key questions addressed in order to understand the emergence of the green food market and the industrial dynamics of green food production behind it in Brazil are: (i) Which type (size, age) of companies are forwarding the green food agenda in Brazil? Particularly what is the role of the big international companies to induce eco-innovation in green food? (ii) To what degree is the green food agenda forwarded by Brazilian versus international companies? (iii) How does the organic chain work? More specifically, to what degree do we see upstream versus downstream green movements? A hypothesis is that Brazil, as the other BRICs rapidly emerging economies, may leapfrog the green economy and more quickly develop well-functioning green food markets as compared to the slow learning curves experienced in the green food market of the developed economies. The recent big crisis in the Brazilian economy and political system may, though, halt this development. On the other hand, the economic crisis may also foster green creativity and entrepreneurship.

Ecological and human health risks associated with abandoned gold mine tailings contaminated soil

Gold mining is a major source of metal and metalloid emissions into the environment. Studies were carried out in Krugersdorp, South Africa, to evaluate the ecological and human health risks associated with exposure to metals and metalloids in mine tailings contaminated soils. Concentrations of arsenic (As), cadmium (Cd), chromium (Cr), cobalt (Co), copper (Cu), lead (Pb), manganese (Mn), nickel (Ni), and zinc (Zn) in soil samples from the area varied with the highest contamination factors (expressed as ratio of metal or metalloid concentration in the tailings contaminated soil to that of the control site) observed for As (3.5x10^2), Co (2.8x10^2) and Ni (1.1x10^2). Potential ecological risk index values for metals and metalloids determined from soil metal and metalloid concentrations and their respective risk factors were correspondingly highest for As (3.5x10^3) and Co (1.4x10^3), whereas Mn (0.6) presented the lowest ecological risk. Human
health risk was assessed using Hazard Quotient (HQ), Chronic Hazard Index (CHI) and carcinogenic risk levels, where values of HQ > 1, CHI > 1 and carcinogenic risk values > 1×10−4 represent elevated risks. Values for HQ indicated high exposure-related risk for As (53.7), Cr (14.8), Ni (2.2), Zn (2.64) and Mn (1.67). Children were more at risk from heavy metal and metalloid exposure than adults. Cancer-related risks associated with metal and metalloid exposure among children were also higher than in adults with cancer risk values of 3×10−2 and 4×10−2 for As and Ni respectively among children, and 5×10−3 and 4×10−3 for As and Ni respectively among adults. There is significant potential ecological and human health risk associated with metal and metalloid exposure from contaminated soils around gold mine tailings dumps. This could be a potential contributing factor to a setback in the health of residents in informal settlements dominating this mining area as the immune systems of some of these residents are already compromised by high HIV prevalence.
Economic and Environmental Impact Trade-Offs Related to In-Water Hull Cleanings of Merchant Vessels

Merchant vessels are equipped with antifouling systems to prevent accumulation of marine organisms on the hull—a phenomenon known as fouling. In many cases, however, fouling accumulates and in-water hull cleaning is required. Hull cleanings are part of a hull management scheme, and although they are an established practice, their associated environmental and economic trade-offs and conflicts have remained largely unexplored. The purpose of this article is to quantitatively assess both economic and environmental impacts of hull management schemes on the operation of tanker vessels. After identifying induced and avoided costs and environmental impacts from the hull management system, we used both temporally and spatially distributed models to capture the degradation of the antifouling system as well as the global sailing profile of the vessels. Last, we analyzed how each of the modeled impacts varied with the frequency of hull cleanings within the hull management scheme. Our analysis revealed a convex relationship between the frequency of hull cleanings and fuel savings. The higher the frequency of hull cleanings, the less fuel savings can be achieved per cleaning. In terms of costs, from some point on the costs of the service are likely to offset the savings—especially if fuel prices are low. In regards to climate change, avoided emissions due to fuel savings are likely to outweigh the limited impacts from the service itself. Last, while ecosystem impacts from marine, terrestrial, and freshwater eco-toxicity are likely to increase from hull cleanings, they are subject to high uncertainties.

Economies of scale in biogas production and the significance of flexible regulation
Biogas production is characterised by economies of scale in capital and operational costs of the plant and diseconomies of scale from transport of input materials. We analyse biogas in a Danish setting where most biogas is based on manure, we use a case study with actual distances, and find that the benefits of scale in capital and operational costs dominate the diseconomies of increasing transport distances to collect manure. To boost the yield it is common to use co-substrates in the biogas production. We investigate how costs and income changes, when sugar beet is added in this case study, and demonstrate that transport cost can be critical in relation to co-substrates. Further we compare the new Danish support for upgraded biogas with the traditional support for biogas being used in Combined Heat and Power production in relation to scale economies. We argue that economies of scale is facilitated by the new regulation providing similar support to upgraded biogas fed into the natural gas grid, however in order to keep transport costs low, we suggest that the biogas plants should be allowed to use and combine as many co-substrates as possible, respecting the sustainability criteria regarding energy crops in Danish legislation.

Educating reflective practitioners in large classrooms

Projects abound in society, and turned from an 'accidental profession' to an attractive career path (Pinto & Kharbanda, 1995). In this line, engineers and engineering students are increasingly recognizing the criticality of project management to their own profession. The consequence is that we need to educate an increasing number of students in project management. At the Technical University of Denmark (DTU) - one of the leading engineering universities in Scandinavia - the number of students taking our courses has increased organically from 150 to over 300 in the last 5 years - a number that is believed to grow even further in the coming years. We thus face the challenge of educating an increasing number of students. One alternative is a focus on traditional learning methods, multiple-choice exams, and a deterministic learning path. However, such tactic is unlikely to develop the reflective practitioner that are required in practice, as seminally argued by Schön (Schön, 1983, 1987), and also applied and argued to project management specifically (Crawford, Morris, Thomas, & Winter, 2006). This hands-on section will describe and analyze our experience – successes and failures – our program to change education of project engineers at DTU with the vision to educate large number of students and enable them to reflect and experience how to DO projects, as oppose to teaching normative tools and techniques. This hands-on section will facilitate discussion about practices to encourage the development of reflective practitioners in large classrooms. It will do so by creating a context for you to experience being a student in a large classroom, and hence being detached from the ‘actual author of the work’. Akin blended learning strategies, you will watch an introductory video, and you will do individual and group exercises, discussing your experiences and this experience of being detached from the ‘teachers’. The discussion will be facilitated by another person (instead of the authors), which will act like a 'teaching assistant', as students experience in large classrooms. We will instruct this other person, but will not be there in the discussions itself. We then join by the end of the discussion, when we will close the session sharing our practices and experiences in dealing with large classrooms. Our work makes two key contributions. First, it points to some pragmatic struggles directly from the classroom, when attempting to reach out to large number of students, while not compromising on a practice approach to projects, and still carrying out an active research career. Second, it positions the relevance of a holistic and systemic view on university education of project managers to engineers.

Effects of carbon fibres on the life cycle assessment of additively manufactured injection moulding inserts for rapid prototyping
A life cycle assessment was conducted to evaluate the global warming potential and human toxicity of injection moulding processes applying newly developed tool inserts produced with vat polymerisation. The inserts were subject to increasing content of carbon fibres to improve their mechanical properties and lifetime. The additively manufactured inserts are compared to the standard materials steel, aluminium and brass. The investigated part of the production and prototyping phase considers the insert itself, the moulded part, and resulting waste material of the injection moulding process.
Electric vehicles and India's low carbon passenger transport: A long-term co-benefits assessment

Electric vehicles have attracted the attention of India's policy makers as clean technology alternatives due to their multiple advantages like higher efficiency and lower air pollution in short to medium term and reduced CO2 emissions as electricity gets decarbonized in the long-run under low carbon scenarios. This paper uses an energy system model ANSWER-MARKAL to analyse the role of electric vehicles (EV) in India. The modelling assessment spans the period 2010 to 2050 and analyses future EV demand in India under three scenarios: i) a 'Reference' scenario which includes the continuation of existing EV policies as outlined in India's Intended Nationally Determined Contribution (INDC); ii) a 'EV policy' scenario which, in line with India's INDCs, follows targeted supply-side push policies for EVs, but without the budget constraints; and iii) a 'low carbon' scenario which uses an exogenous price for CO2 in line with the global target of 2 °C temperature stabilization. The scenarios analysis delineates penetration of EVs and their co-benefits as well as co-costs. The co-benefits relate to local air quality, national energy security and CO2 emissions in India whereas the co-costs (risks) are related to sourcing of raw materials for batteries and battery reprocessing and disposal.

The findings show that: i) in the reference scenario, the EVs 2-wheelers will achieve a significant share by 2050. Electric 4-wheelers though would have a small share even in 2050; ii) EV push policies though lead to significant diffusion of electric 2-wheelers in India by 2030. These policies enhance diffusion of electric 4-wheelers only if financial incentives are sustained in the long-term, iii) the application of global carbon price on the Indian economy in the 2 °C stabilization scenario increases competitiveness of EVs and results in near total share of electric 2-wheelers by 2030 and a sizable share of electric 4-wheelers by 2050. The high and rising carbon price in low carbon scenario cause deep decarbonisation of electricity and enables EVs to deliver deep cut in CO2 emissions. The results show asymmetry in the impacts of national and global policies on co-benefits from EV. The EV supply-push policies deliver moderate benefits vis-à-vis air pollution and energy security indicators but make insignificant contribution CO2 emissions reduction. On the other hand, the global carbon price in the global 2 °C stabilization scenario delivers sizable co-benefits vis-à-vis all three indicators. This asymmetry reveal important policy insights: i) the policy sequencing is vital to gain co-benefits, ii) EV technology push policies are good for creating early domestic market for a clean vehicle technology but they may not deliver sizable co-benefits vis-à-vis CO2 emissions which are global externalities, and iii) implementing strong climate policies early would lead to EVs delivering high co-benefits, in case of India, vis-à-vis all three indicators.
Empirical analyses of a choice model that captures ordering among attribute values

In most choice models, the evaluation of attributes depends on differences of attribute values. Some research, mainly in marketing and psychology, suggests that the differences do not give the full picture of how decision makers evaluate choice alternatives, e.g. some decision makers may penalise an alternative additionally because it has the highest price. In this paper, we specify a discrete choice model that takes into account the ordering of attribute values across alternatives. This model is used to investigate the effect of attribute value ordering in three case studies related to alternative-fuel vehicles, mode choice, and route choice. In our application to choices among alternative-fuel vehicles, we see that especially the price coefficient is sensitive to changes in ordering. The ordering effect is also found in the applications to mode and route choice data where both travel time and cost sensitivities are affected by the ordering. Overall, the ordering effects have implications for both parameter estimates and the evaluation of willingness-to-pay measures.

Enabling Bus Transit Service Quality Co-Monitoring Through Smartphone-Based Platform

The growing ubiquity of smartphones offers public transit agencies an opportunity to transform ways to measure, monitor, and manage service performance. The potential of a new tool is demonstrated for engaging customers in measuring satisfaction and co-monitoring [Editor's note: This is the authors' word, meaning "agencies using public feedback to supplement official monitoring and regulation."] bus service quality. The pilot project adapted a smartphone-based travel survey system, Future Mobility Sensing, to collect real-time customer feedback and objective operational measurements on specific bus trips. The system used a combination of GPS, Wi-Fi, Bluetooth, and accelerometer data to track transit trips while soliciting users' feedback on trip experience. Though not necessarily intended to replace traditional monitoring channels and processes, these data can complement official performance monitoring through a more real-time, customer-centric perspective. The pilot project operated publicly for 3 months on the Silver Line bus rapid transit in Boston, Massachusetts. Seventy-six participants completed the entrance survey; half of them actively participated and completed more than 500 questionnaires while on board either at the end of a trip, at the end of a day, or both. Participation was biased toward frequent Silver Line users, the majority of whom were white and of higher income. Indicative models of user-reported satisfaction reveal some interesting relationships, but the models can be improved by fusing the app-collected data with actual performance characteristics. Broader and more sustained user engagement remains a critical future challenge.
Energy demand, substitution and environmental taxation: An econometric analysis of eight subsectors of the Danish economy

This research contains an econometric analysis of energy demand in trade and industry which allows for substitution between electricity and other energy carriers when relative prices change. The presence of substitution suggests that taxation can be a means of changing the energy input mix in a more environmental-friendly direction. For eight subsectors of the Danish economy, time series (1966–2011) are modeled by means of partial Cointegrated VARs. Long-run demand relations are identified for all subsectors and robust price elasticities are supported in five cases. The results are used in a small impulse–response experiment which suggests a potential for taxation to induce substitution of electricity for fossil-based energy.

Energy supply modelling of a low-CO2 emitting energy system: Case study of a Danish municipality

Municipal activities play an important role in national and global CO2-emission reduction efforts, with Nordic countries at the forefront thanks to their energy planning tradition and high penetration of renewable energy sources. In this work, we present a case study of the Danish municipality of Sønderborg, whose aim is to reach zero net CO2 emissions by 2029. Sønderborg has an official strategic plan towards 2029, which we compared with four alternative scenarios to investigate how the municipality could approach its target in the most energy-efficient and cost-effective way while simultaneously keeping biomass and waste consumption close to the limits of the locally available residual resources. We modelled all sectors of the energy system on the municipal scale, applying a broad range of energy conversion technologies, including advanced biomass conversion technologies and reversible electrolysis. We constructed five scenarios, each representing a different energy mix for Sønderborg’s energy system in 2029. We modelled these scenarios using the mixed-integer linear optimization tool Sifre. We compared the results for the five scenarios using four indicators: annual total system cost, total energy system efficiency, annual net system CO2 emissions and total annual biomass consumption. The results show that scenarios with a high degree of electrification perform better on the selected indicators than scenarios with a high degree of biomass utilization. Moreover, the incorporation of advanced conversion technologies such as electrolysis, fuel cells and methanol production further reduces both the total system cost and net CO2 of the highly electrified energy system. Our sensitivity analysis demonstrates that scenarios with a low biomass consumption and a high degree of electrification are less dependent on changes in energy prices. We conclude that in order to achieve their CO2 emission goals in the most energy-efficient, cost-effective and sustainable way, municipalities similar to Sønderborg should compare a wide range of energy system configurations, for example, scenarios with a high degree of electrification and a limited biomass use.

Engineering Value-Effective Healthcare Solutions: A Systems Design Perspective

Our modern healthcare systems commonly face an important dilemma. While they depend on innovation to provide continuously greater healthcare value, they also struggle financially with the burden of adopting a continuous flow of new products and services. Although several disruptive healthcare models, i.e. decentralised, personalised, pervasive, connected, and stratified, promise to relieve some of this tension, they do not per se guarantee optimal value generation. We argue that systems thinking and engineering design can remedy this limitation. We support this claim by making the case of Design for Evolvability and by elaborating on two examples: MRI systems and Point-of-Care in-vitro diagnostics solutions. We specifically argue that Design for Evolvability can realign the agendas of various healthcare stakeholders, serving both individual and national interests. We finally acknowledge the limitations of current engineering design practices and call for new theoretical and empirical research initiatives taking a systems perspective on healthcare product and service design.

Enterprise architecture management: Toward a taxonomy of applications

Despite the growing interest in enterprise architecture management, researchers and practitioners lack a shared understanding of its applications in organizations. Building on findings from a literature review and eight case studies, we develop a taxonomy that categorizes applications of enterprise architecture management based on three classes of enterprise architecture scope. Organizations may adopt enterprise architecture management to help form, plan, and implement IT strategies; help plan and implement business strategies; or to further complement the business strategy-formation process. The findings challenge the traditional IT-centric view of enterprise architecture management application and suggest enterprise architecture management as an approach that could support the consistent design and evolution of an organization as a whole.
Environmental impacts of barley cultivation under current and future climatic conditions

The purpose of this work is to compare the environmental impacts of spring barley cultivation in Denmark under current (year 2010) and future (year 2050) climatic conditions. Therefore, a Life Cycle Assessment was carried out for the production of 1 kg of spring barley in Denmark, at farm gate. Both under 2010 and 2050 climatic conditions, four subscenarios were modelled, based on a combination of two soil types and two climates. Included in the assessment were seed production, soil preparation, fertilization, pesticide application, and harvest. When processes in the life cycle resulted in co-products, the resulting environmental impacts were allocated between the main product and their respective by-products using economic allocation. Impact assessment was done using the ReCiPe (H) methodology, except for toxicity impacts, which were assessed using USEtox. The results show that the impacts for all impact categories, except human and freshwater eco-toxicity, are higher when the barley is produced under climatic circumstances representative for 2050. Comparison of the 2010 and 2050 climatic scenarios indicates that a predicted decrease in barley yields under the 2050 climatic conditions is the main driver for the increased impacts. This finding was confirmed by the sensitivity analysis. Because this study focused solely on the impacts of climate change, technological improvements and political measures to reduce impacts in the 2050 scenario are not taken into account. Options to mitigate the environmental impacts are discussed.

Environmental impacts of electricity self-consumption from organic photovoltaic battery systems at industrial facilities in Denmark

Organic photovoltaics (OPV) show promise of greatly improving the environmental and economic performance of PV compared to conventional silicon. Life cycle assessment studies have assessed the environmental impacts of OPV, but not under a self-consumption scheme for industrial facilities. We investigate the life cycle environmental impacts of electricity self-consumption from an OPV system coupled with a sodium/nickel chloride battery at an iron/metal industry in Denmark. Results show that an OPV system without storage could decrease the carbon footprint of the industry; installation of the battery increases climate change and human toxicity impacts. We discuss sensitive modelling parameters and provide recommendations.

To move towards environmentally-sustainable transport systems, electric vehicles (EVs) are increasingly seen as viable alternatives to internal combustion vehicles (ICVs). To ensure effectiveness of such deployment, holistic assessments of environmental impacts can help decision-makers determine optimised urban strategies in a long-term perspective. However, explicit guidance and conduct of such assessments are currently missing. Here, we therefore propose a framework using life cycle assessment that enables the quantification of environmental impacts of a transport system at full urban scale from a fleet-based, foresight perspective. The analysis of the passenger car fleet development in the city of Copenhagen for the years 2016-2030 is used as a proof-of-concept. We modelled and compared five powertrain
technologies, and we assessed four fleet-based scenarios for the entire city. Our results showed relative environmental benefits from range-extended and fuel-cell EVs over ICVs and standard EVs. These results were found to be sensitive to local settings, like electricity grid mix, which could alter the relative environmental performances across EV technologies. The comprehensive framework developed here can be applied to other geographic areas and contexts to assess the environmental sustainability of transport systems.

Environmental impacts of producing bioethanol and biobased lactic acid from standalone and integrated biorefineries using a consequential and an attributional life cycle assessment approach

This study evaluates the environmental impacts of biorefinery products using consequential (CLCA) and attributional (ALCA) life cycle assessment (LCA) approaches. Within ALCA, economic allocation method was used to distribute impacts among the main products and the coproducts, whereas within the CLCA system expansion was adopted to avoid allocation. The study seeks to answer the questions (i) what is the environmental impacts of process integration?, and (ii) do CLCA and ALCA lead to different conclusions when applied to biorefinery?. Three biorefinery systems were evaluated and compared: a standalone system producing bioethanol from winter wheat-straw (system A), a standalone system producing biobased lactic acid from alfalfa (system B), and an integrated biorefinery system (system C) combining the two standalone systems and producing both bioethanol and lactic acid. The synergy of the integration was the exchange of useful energy necessary for biomass processing in the two standalone systems. The systems were compared against a common reference flow: "1 MJ EtOH + 1 kg LA", which was set on the basis of products delivered by the system C. Function of the reference flow was to provide service of both fuel (bioethanol) at 99.9% concentration (wt. basis) and biochemical (biobased lactic acid) in food industries at 90% purity; both products delivered at biorefinery gate. The environmental impacts of interest were global warming potential (GWP100), eutrophication potential (EP), non-renewable energy (NRE) use and the agricultural land occupation (ALO). Regardless of the LCA approach adopted, system C performed better in most of the impact categories than both standalone systems. The process wise contribution to the obtained environmental impacts also showed similar impact pattern in both approaches. The study also highlighted that the recirculation of intermediate materials, e.g. C5 sugar to boost bioethanol yield and that the use of residual streams in the energy conversion were beneficial for optimizing the system performance.

Environmental impacts of stormwater management and pollutant discharges

General information

Environmental impacts of stormwater management and pollutant discharges

Stormwater management systems are necessary to protect people and assets from flooding and pollution, especially in densely built, sealed urban areas. The possible solutions range from underground pipes and basins, where rain water is often handled together with wastewater, to local and multi-functional solutions, e.g. rain beds or retention lakes. Ideally, these solutions are not only economically, but also environmentally sustainable. Risk assessments are sometimes carried out, e.g. to determine the effect of discharges during extreme events, but they lack a holistic perspective: While pollutants in runoff are one possible source of (local) environmental impacts, the stormwater management system itself is a source of emissions. Raw material extraction, construction, operation, renewal, and disposal all cause environmental impacts at a more regional or even global scale. These impacts can be quantified using life cycle assessment, which on the other hand usually neglects the impacts from local emissions, even though these may potentially be significant. By integrating local emissions into the assessment, we are able to quantify the total environmental impacts of stormwater management solutions.

We have tested the approach using a sub-catchment of Copenhagen. The existing stormwater management system has to be adapted to climatic changes to maintain existing flood safety levels. The environmental impacts from both local and global emissions over a period of 100 years have been quantified using life cycle assessment. The inventory for the assessment is based on an extensive literature research, planning documents and expert interviews. Here, we focus on the ecotoxicity impacts: The impact over the whole life cycle of the system, excluding local emissions, is 14 mio comparative toxic units (CTUe). This ecotoxicity impact is mainly caused by the emission of metals. Metals are, however, also important pollutants in stormwater runoff. In Copenhagen, the emission of stormwater pollutants from runoff are found to cause additional impacts of 19 mio CTUe when discharged directly to freshwater. If the water first infiltrates through soil, the impacts are significantly lower (10 mio CTUe). The stormwater system itself is passive, and mainly causes impacts during construction, while runoff goes through the system constantly over 100 years, which explains the large difference in impacts. The results are characterized by a high uncertainty, which is caused by large ranges in measured concentrations in literature (up to 5 orders of magnitude). Limiting these uncertainties is the subject of ongoing research.

Our results highlight the importance of including local emission of toxic compounds in stormwater management systems. Often, an increase in global emission, e.g. through the construction of treatment facilities, will lead to reduced local impacts, and vice versa. By taking into account both local and global impacts, stormwater management systems can be optimized holistically to minimize environmental impacts and create more sustainable stormwater management systems.

Environmental Labels and Declarations

Based on the terminology and structure developed by the International Organization for Standardization, a description is given on the types of ecolabels that build on life cycle assessments. Focus is on type I labels that point out products and services with an overall environmental preferability within a specific product category. Type I labels include official labels set up by government and international institutions. Examples are given on operation of labelling schemes, development and focus area for criteria that must be met to obtain a label, effects on environment and legislation of labelling, the use of ecolabels in marketing, and the way ecolabels help build a market for “greener products”. Type III labels—or Environmental Product Declarations—are also briefly described with indicative examples from the building sector, a declaration for office furniture, and an introduction is given to the European Commission’s programme for product—and organisational environmental footprints.

Environmental life cycle assessment of producing willow, alfalfa and straw from spring barley as feedstocks for bioenergy or biorefinery systems

The current study aimed at evaluating potential environmental impacts for the production of willow, alfalfa and straw from spring barley as feedstocks for bioenergy or biorefinery systems. A method of Life Cycle Assessment was used to evaluate based on the following impact categories: Global Warming Potential (GWP100), Eutrophication Potential (EP), Non-Renewable Energy (NRE) use, Agricultural Land Occupation (ALO), Potential Freshwater Ecotoxicity (PFWTox) and Soil quality. With regard to the methods, soil organic carbon (SOC) change related to the land occupation was calculated based on the net carbon input to the soil. Freshwater ecotoxicity was calculated using the comparative toxicity units of the active ingredients and their average emission distribution fractions to air and freshwater. Soil quality was based on the change in the SOC stock estimated during the land use transformation and land occupation. Environmental impacts for straw were economically allocated from the impacts obtained for spring barley. The results obtained per ton dry matter showed a lower carbon footprint for willow and alfalfa compared to straw. It was due to higher soil carbon sequestration and lower N2O emissions. Likewise, willow and alfalfa had lower EP than straw. Straw had lowest NRE use compared to other biomasses. PFWTox was lower in willow and alfalfa compared to straw. A critical negative effect on soil quality was found with the spring barley production and hence for straw. Based on the energy output to input ratio, willow performed better than other biomasses. On the basis of carbohydrate content of straw, the equivalent dry matter of alfalfa and willow would be requiring higher. The environmental impacts of the selected biomasses in biorefinery therefore would differ based on the conversion efficiency, e.g. of the carbohydrates in the related biorefinery processes.
Environmental life cycle assessments of producing maize, grass-clover, ryegrass and winter wheat straw for biorefinery

The aim of this study is to assess the potential environmental impacts of producing maize, grass-clover, ryegrass, and straw from winter wheat as biomass feedstocks for biorefinery. The Life Cycle Assessment (LCA) method included the following impact categories: Global Warming Potential (GWP100), Eutrophication Potential (EP), Non-Renewable Energy use (NRE), Potential Fresh Water Ecotoxicity (PFWTox) and Potential Biodiversity Damages (PBD). The results showed that GWP100 (in kg CO₂ eq, including contribution from soil carbon change) for producing 1 ton of dry matter (t DM) was highest for ryegrass, grass-clover and maize, and lowest for straw. The carbon footprints of ryegrass, grass-clover and maize were affected by including the contribution from soil organic carbon (SOC) changes. Nitrous oxide emissions and emissions related to the production of agro-chemicals (including N-fertilizer) were other hotspots in the carbon footprint. The EP calculated per t DM was highest for grass-clover, ryegrass and maize, and was lowest for straw. NRE use (MJ eq/t DM) was highest for ryegrass, grass-clover and maize and lowest for straw. Major hotspots were diesel use for field operations and agro-chemicals production. The PBD, expressed as Potentially Disappeared Fraction (PDF) showed the highest adverse impact to biodiversity in maize, followed by straw, whereas the results showed relatively lower impact for ryegrass and grass-clover. The PFWTox (CTUe/t DM), at farm level was highest for straw, followed by maize, whereas the values were significantly lower for grass-clover and ryegrass. These variations in ranking of the different biomasses productions using different impact categories for environmental performance showed that it is important to consider a wider range of impact categories for assessing environmental sustainability.

Environmental performance of gasified willow from different lands including land-use changes

A life-cycle assessment (LCA) of a low-input, short rotation coppice (SRC) willow grown on different Danish lands was performed. Woodchips are gasified, producer gas is used for co-generation of heat and power (CHP) and the ash-char output is applied as soil amendment in the field. A hybrid model was developed for the estimation of greenhouse gas (GHG) emissions from indirect land-use changes (iLUC) induced by willow cropping on arable land. For this, area expansion results from a general equilibrium economic model were combined with global LUC trends to differentiate between land transformation (as additional agricultural expansion, in areas with historical deforestation) and occupation (as delayed relaxation, DR, in areas with historical land abandonment) impacts. A biophysical approach was followed to determine the iLUCfood emissions factor from marginal grassland. Land transformation impacts were derived from latest world deforestation statistics, while a commercial feed mix of equivalent nutritive value was assumed to substitute the displaced grass as fodder. Intensification effects were included in both iLUC factors as additional N-fertilizer consumption. Finally, DR impacts were considered for abandoned farmland, as a relative C stock loss compared to natural regeneration. iLUC results show that area related GHG emissions are dominant (93% of iLUCfood and 80% of iLUCfeed), transformation being more important (82% of iLUCfood) than occupation (11%) impacts. LCA results show that CHP from willow emits 4,047 kg CO2-eq haoccup−1 (or 0.8 gCO2-eq MJ−1) when grown on arable land, while sequestering 43,745 kg CO2-eq haoccup−1 (or -10.4 gCO2-eq MJ−1) when planted on marginal pastureland, and 134,296 kg CO2-eq haoccup−1 (or -31.8 gCO2-eq MJ−1) when marginal abandoned land is cultivated. Increasing the bioenergy potential
without undesirable iLUC effects, especially relevant regarding biodiversity impacts, requires that part of the marginally used extensive grasslands are released from their current use or energy cropping on abandoned farmland incentivized.

Environmental screening of novel technologies to increase material circularity: A case study on aluminium cans
It is undisputed that the recycling of aluminium is desirable as long as the environmental and economic implications of its reintegration do not exceed the burdens of its primary production. The efficiency of any aluminium recycling system can be expressed by the total material losses throughout the entire process chain, ideally reaching 0%, thus equivalent to 100% metal recovery. However, in most cases metals are recycled in open/cascade recycling loop where dilution and quality losses occur. Innovations in aluminium beverage can (ABC) design as well as in sorting and recycling technologies have the potential to increase recyclability and avoid downcycling issues due to mixed alloy scrap streams. By means of Life Cycle Assessment (LCA) seven scenarios, comprising specific systemic changes, are compared to the current recycling practice of the used beverage can in the UK. The End-of-Life modelling of recycling is performed in accordance with the equal share method to account for impacts both on the recyclability and the recycled content. The results confirm the primary aluminium production and energy consumption in the ABC production as the hotspots in the life cycle of the ABC. The toxicity and energy-related impact categories show the highest susceptibility to increasing recycled content and recycling rate, while the technological novelties show little effect. In terms of abiotic resource depletion the introduction of novel technologies could have the potential to retain quality of the aluminium alloys by either establishing dedicated waste streams or upgrading the aluminium scrap by dedicated sorting strategies.
Errors, lies and misunderstandings: Systematic review on behavioural decision making in projects

This paper provides a systematic review of the literature on behavioural decision making in projects. The field is blooming, and given the relevance of decisions in projects and the strong theoretical foundations of behavioural decision making, it offers to contribute to practice and theory in projects and beyond. However, the literature is fragmented and draws only on a fraction of the recent, insightful, and relevant developments on behavioural decision making. This paper organizes current research in a conceptual framework rooted in three schools of thinking—reductionist (on cognitive limitations—errors), pluralist (on political behaviour—lies), and contextualist (on social and organizational sensemaking—misunderstandings). Our review suggests avenues for future research with a wider coverage of theories in cognitive and social psychology and critical and mindful integration of findings and concepts across three schools.

Aiming for a more efficient use of resources, the European Commission encourages the use of animal manure as a fertilizer providing nutrients and organic matter to improve crop productivity and soil fertility [1,2]. However, livestock manure contains traces from pathogens, veterinary medicines, and feed additives (e.g., antibiotics and heavy metals), which may cause damages to ecosystems and human health. To prevent large damages from happening, tools such as environmental risk assessment (ERA) and life cycle assessment (LCA) are used to evaluate the environmental risks and impacts of the pollutant emissions resulting from manure application. Both methodologies first require an estimation of the emissions to soil as part of their respective stages of exposure assessment and life cycle inventory analysis.

To provide consistent support to high-level policy-makers, e.g., supporting regulations on the use of such substances in livestock production, large-scale assessments are required. To date, the total emissions of harmful substances resulting from the application of manure at country level have however been rarely quantified. We therefore developed a framework to estimate these releases to soil in a systematic way. We applied it to emissions of 8 heavy metals (HMs) in 215 countries from 2000 to 2014 and analysed the resulting environmental toxicity-related impacts based on life cycle impact assessment.

Evaluering climate change mitigation potential of hydrochars: compounding insights from three different indicators

We employed life cycle assessment to evaluate the use of hydrochars, prospective soil conditioners produced from biowaste using hydrothermal carbonization, as an approach to improving agriculture while reusing carbon present in the biowaste. We considered six different crops (barley, wheat, sugar beet, fava bean, onion and lucerne) and two different countries (Spain and Germany), and used three different indicators of climate change: global warming potential (GWP), global temperature change potential (GTP), and climate tipping potential (CTP). We found that although climate change benefits (GWP) from just sequestration and temporary storage of carbon are sufficient to outweigh impacts stemming from hydrochar production and transportation to the field, even greater benefits stem from replacing climate-inefficient biowaste management treatment options, like composting in Spain. By contrast, hydrochar addition to soil is not a good approach to improving agriculture in countries where incineration with energy recovery is the dominant treatment option for biowaste, like in Germany. Relatively small, but statistically significant differences in impact scores were found between crops. Although these conclusions remained the same in our study, potential benefits from replacing composting were smaller in the GTP approach, which due to its long-term perspective gives less weight to short-lived GHGs like methane. Using CTP as an indicator we also found that there is a risk of contributing to crossing of a short-term climatic target, the tipping point corresponding to an atmospheric GHG concentration of 450 ppm CO2 equivalents, unless hydrochar stability in the soil is optimized. Our results highlight the need for considering complementary perspectives that different climate change indicators offer, and overall provide a foundation for assessing climate change mitigation potential of hydrochars used in agriculture.

Evaluating the police service quality for handling traffic crash reporting: A combined MCDA and LCA approach
Purpose The phenomenon of traffic crash under-reporting has been extensively documented in terms of its extent, but not equally analysed in terms of its reasons. As police distrust has been recently identified as a major reason for crash under-reporting, the purpose of this paper is to look at the police service quality for handling the reporting of traffic crashes.
Design/methodology/approach This study introduces a novel approach to evaluate service quality that combines multi-criteria decision analysis (MCDA) with latent class analysis (LCA). Moreover, this study presents the design of a web-based survey on the basis of the SERVQUAL approach to detecting strengths, opportunities and threats with crash reporting to the police at a strategic level. Transportation stakeholders (e.g. researchers, authorities, consultants, NGO representatives, suppliers) with an interest in traffic safety in Denmark participated in the survey that yielded 86 complete responses. Findings The novel approach was successfully applied and its implementation demonstrated the usefulness of the tool even in countries with a high police service. Results showed that the participating stakeholders perceived human factors as more important than physical factors in order to increase the crash reporting, with responsiveness as the most important and tangibles as the least important dimensions. Nevertheless, most stakeholders viewed a mixture of human and physical factors as crucial to increase crash reporting rates. Originality/value This study advances the knowledge about police service quality with a novel expert-based decision support tool based on SERVQUAL, MCDA and LCA, demonstrates its applicability in countries with a high-police service, and opportunities and barriers for increasing the crash reporting rate.
Evolution of the Jatropha Biofuel Niche in Ghana

This article draws on the multi-level perspective (MLP) and global value chain (GVC) frameworks to analyse the drivers and trajectories of foreign private investment in biofuel production in Ghana. The analyses are based on a narrative of the evolution of a niche for jatropha production in Ghana spanning the period 1995–2004 and including detailed company
case studies. Relating to the MLP framework the factors analysed influencing internal niche processes are alignment of expectations, network formation, and learning and knowledge sharing, while those relating to the GVC framework are value chain attributes, including chain structure, governance, ownership, and access to land and capital. The study identifies significant entry barriers to establishing new agriculture-based value chains for global biofuel markets, especially high volume requirements, high capital needs and international market risks, which contributed to the collapse of the jatropha sector in Ghana and thus to the failure to capitalise on the initially high expectations of biofuel production. We also found a low level of learning and knowledge sharing between jatropha niche actors in Ghana, which, alongside weak public R&D support, reduced access to locally specific technical and managerial information. The report presents an example of non-evolutionary niche development, which goes beyond the European experience of industrial niche development on which the MLP framework was first established. The importance of investors and policy at different levels of the value chain illustrates the synergies that may be obtained from combining the MLP and GVC frameworks in research on energy transitions in developing countries.

Expatriate academics and perceptions of organisational support
Research on Perceived Organisational Support (POS) rarely focuses on the potential gap between employee perceptions versus the support the organisation purports to offer. An understanding of this may provide greater insight into the interventions a university should be making if it hopes to improve retention of its expatriate academics. By analysing qualitative responses to a written questionnaire, this paper explores the perceptions of organisational support held by 163 expatriate academics employed at a large international Danish university, and compares these perceptions to the support the university claims to offer. Our study reveals that, in the case of expatriate academics, even extensive offerings of organisational support can be insufficient if the existence and specific benefits of the support are not adequately communicated, and if the academics do not trust the source of the support on offer. Theoretical and practical implications are discussed.

Experiences with auctions for renewable energy support

Auctions is an increasingly popular instrument for introducing competitiveness in the support schemes for renewable energy, however, designing successful auctions appears to be a challenge. Policy makers seeking to introduce auctions are faced with a range of design choices, which may affect the auction outcome significantly. This paper investigates the past experiences with auction implementations in 13 countries. We highlight popular design choices and evaluate auction performances based on a set of assessment criteria. We find that as a market-based support mechanism auctions can help driving down support costs, however, they are also prone to design errors. Adjusting the auction design to the specific conditions (national and marked) is a key parameter for success.
further research is required to address data quality, pre-processing, and applicability, before considering data submitted under REACH as a data source for use in LCIA, and also to explore additionally available data sources, published studies, and reports.

Exploring the dynamics of firm and innovation community collaboration: A complex love story
The classic fairy tale of The Little Mermaid (Andersen 1836) tells the story of the little mermaid falling in love with a prince from the unknown and different world over the sea inhabited by humans. She tries to access this world by exchanging her voice for a pair of human legs. Although she accepts the fierce pain of walking, she can never fully transcend the boundaries of their separate worlds and when the prince does not return her love, she dissolves into foam. However, instead of ceasing to exist, the little mermaid transforms into a new spiritual form floating above the stars. She will never be able to be with her prince and satisfy her desire for the human world, but her transformation renders it possible to obtain an immortal soul and rise up into the kingdom of God.

Exploring Uncertainty Perception as a Driver of Design Activity
This paper investigates uncertainty perception as a general driver of individual design activity. An observation based protocol study is used to explore the interaction between uncertainty perception and three core actions connected in design activity: information action, knowledge sharing action, and representation action. We bring together prior works on uncertainty perception in the design and management literatures to derive three contributions. First, we describe how uncertainty perception is associated with activity progression, linking all three core actions. Second, we identify characteristic patterns of interaction between uncertainty perception and activity. Third, we decompose uncertainty perception to further explain its role in driving design activity. This extends prior research on design activity, and supports a number of theoretical and empirical implications.

FDG at 7.8 MeV

I here report the fundamental performance of a new generation of compact medical cyclotrons for hospital-based PET tracer manufacture, exemplified with the FDG production numbers achieved by the first prototype of the GE GenTrace cyclotron. The proton energy is 7.8 MeV. After 3 years of extensive testing in a “physics lab” setting, which is door-to-door with our normal GMP production suite, I can now conclude that this cyclotron in conjunction with a standard GE Fastlab chemistry box easily achieves significant, reliable and compliant FDG output surpassing 15 GBq per batch at EOS, after 2 hours bombardment time. The details are reported below.

Feasibility of wind power integration in weak grids in non-coastal areas of Sub-Saharan Africa: the case of Mali

Installed wind capacity in Africa has grown rapidly the last few years, and by late 2016 had reached about 4.8 GW. However, so far few investments have been made in inland localities due to the generally lower wind potential. This paper therefore explores if and to what extent it is possible to establish economically feasible wind-power plants in countries with lower wind potential. To address this question, the paper provides a combined wind resource mapping and a pre-feasibility study for grid integration of wind power at four specific sites in Mali. The study finds that Mali has generally poor wind conditions, with average wind speeds of below 5 m/s at 50 m above ground level in the south, while there are larger areas in the northern part with average wind speeds of above 7 m/s at 50 m above ground level. Overall the research shows that in countries with generally poor wind conditions, such as in the southern part of Mali, it is possible to identify a limited number of sites with local speed-up effects situated close to the existing grid, at which there are options for undertaking medium-size wind-power projects that would be economically feasible at current crude oil prices of 50 USD/barrel.

Flexibility-friendly support policies: A Nordic and Baltic perspective

This paper introduces the concept of flexibility-friendly support policies, i.e. state of-the-system-dependent subsidies given to producers of electricity who base their output on renewable energy sources (RES). Such policies increase with demand,
decrease with the availability of Variable Renewable Energy (VRE) producers and, overall, follow the power system’s residual load. The paper presents a microeconomic framework to analyze this and other desirable properties of support mechanisms. To illustrate the concept, it uses the present-day policies of Nordic and Baltic countries (Denmark, Estonia, Finland, Latvia, Lithuania, Sweden and Norway) as a case study.

**Flood management in urban Senegal: an actor-oriented perspective on national and transnational adaptation interventions**

In Senegal, considerable development assistance has been allocated to addressing the problem of repeated flooding in urban areas, involving changing thematic objectives, from short-term disaster relief to wide-ranging sanitation and drainage programmes. In spite of these numerous flood management interventions, the number of flood victims in Senegal’s urban centres has increased steadily since 1999. This article contributes empirically and conceptually to recent studies highlighting poor national disaster risk-management frameworks in West Africa, by investigating how floods have been managed in Senegal and why this management has not led to the results expected by the population. The article finds that the configuration of flood management policies and programmes in urban Senegal points towards three key intertwined issues which have influenced the limited achievements of flood management in urban areas. These include, but are not restricted to, the political and personal appropriation of flood management-related processes, the reinforcement of the dichotomy between central government and municipalities, and a fragmented institutional framework with overlapping institutions.
Flow Formulations for Curriculum-based Course Timetabling

In this paper we present two mixed-integer programming formulations for the Curriculum based Course Timetabling Problem (CTT). We show that the formulations contain underlying network structures by dividing the CTT into two separate models and then connect the two models using flow formulation techniques. The first mixed-integer programming formulation is based on an underlying minimum cost flow problem, which decreases the number of integer variables significantly and improves the performance compared to an intuitive mixed-integer programming formulation. The second formulation is based on a multi-commodity flow problem which in general is NP-hard, however, we prove that it suffices to solve the linear programming relaxation of the model. The formulations show competitiveness with other approaches based on mixed-integer programming from the literature and improve the currently best known lower bound on one data instance in the benchmark data set from the second international timetabling competition. Regarding upper bounds, the formulation based on the minimum cost flow problem performs better on average than other mixed integer programming approaches for the CTT.

FM knowledge – theoretical foundation and application in practice.

The idea behind this special issue can be dated back to a whole day workshop that I organised on 7 November 2012 at our Centre for Facilities Management – Realdania Research (CFM), Technical University of Denmark. The title of the workshop was "Added Value and Advancements in FM knowledge". The situation was that I since 2009 had chaired a European research group in EuroFM concerning "The Added Value of FM". In spring 2012 this collaborative research work had culminated in publishing an anthology (Jensen et al., 2012). The purpose of the workshop was to discuss and possibly decide, whether we should continue collaborative research in the same vein or change direction towards other areas of joint interest. The 9 participants were from CFM and our closest collaboration partners in Denmark, Finland, Netherlands, Norway, Sweden, Switzerland and UK.
Foresighting for Inclusive Development

We propose that foresight can contribute to inclusive development by making innovation systems more inclusive. Processes of developing future oriented innovation policies are often unsuccessful and rarely inclusive. We conceptualize such processes as foresighting. We focus on how the ex-ante design of policymaking processes affects the actual process with a focus on inclusion, and we discuss how it affects policy effectiveness and innovation system transformation. Our argument is that processes of policymaking must be inclusive to affect and transform innovation systems because a set of distributed actors, rather than ministries and innovation agencies, is the gatekeepers of change. From this perspective, inclusion is a precondition rather than an obstacle for transformation. Based on the notion of innovation system foresight, we develop an analytical framework that we use to study design and processes in foresight cases in two emerging economies: Brazil and South Korea. We conclude that better systemic and innovation oriented foresight is needed to enhance inclusive development.

Forks in the road to e-mobility: An evaluation of national policy mixes in northwest Europe

Passenger mobility is one of the significant and growing contributors to global climate change. Also, local air pollution limit values for PM10 and NOx are regularly exceeded at traffic monitoring sites across the European Union (Althaus 2011). Policymakers have recognized these problems associated with internal combustion engine (ICE) car mobility and implemented various policies, most notably regulations regarding vehicle emissions at EU level and also stimulation of low carbon fuel and propulsion systems at both EU and national level, including electric mobility. This paper evaluates how policy shaped the emergence of electric mobilities in three countries. Since there is not just one instrument affecting electric mobility, but rather a range of policy instruments (i.e. both newly introduced and established ones that affect all cars), this requires understanding the interactions between these instruments. Other studies have evaluated the effect of financial instruments or recharging infrastructure separately (e.g. Sierzchula et al 2014 through correlation analysis), but such studies neglect or ignore interaction effects between instruments. Our aim is to highlight interaction effects and contribute empirically to the literature on policy mixes. The research question is: what are effective and (in)efficient policy mixes for electric mobility and why? We use the framework of Givoni et al (2013) to analyse the interaction effects of policy instruments. They distinguish three types of relationships: (1) preconditioned linkages, where the successful implementation of one measure is completely contingent on another; (2) synergetic linkages, where the functional capacity of a measure is enhanced by another, and; (3) contradictory linkages, where two or more countervailing policy measures undermine the functional capacity of one or both. For each country, policy and related reports are reviewed, policy mixes presented and patterns of full battery-electric vehicle (FBEV) diffusion compared. Moreover, we conducted a set of interviews and expert roundtables in each country in order to record stakeholder views on policy interactions and the subsequent effect on the effectiveness and efficiencies of the policy mixes. This included 18 semi-structured personal interviews with policy makers, researchers, NGOs, project managers, business employees, and branch organizations in Denmark (11), Norway (8) and the Netherlands (8) during 2013-2015. Interviews were conducted both with people directly involved in policy decisions and implementation ('insiders') and with experts and stakeholders with good knowledge of e-mobility but not directly engaged in their making or implementation ('outsiders'). Norway exhibits high – and rapidly growing – levels of penetration of FBEVs, whereas Denmark presently shows limited FBEV adoption. In the Netherlands, e-mobility has grown relatively fast (although for about 85% plug-in hybrid, not FBEVs), and not only in terms of use, but also in business development associated with the recharging infrastructure. The first finding of this paper is that demand side policies, in combination with the creation of a charging infrastructure can be considered preconditions for FBEV in view of the very small diffusion in countries where one of those elements is missing, such as Estonia for example. A variety of demand-side measures, such as free toll roads and free parking, free use of bus lanes, in combination with sales tax and annual road tax exemption, contributed significantly to the fast growth of FBEV sales in Norway. Contradictory effects were observed in the Netherlands, where the support for cleaner (more fuel-efficient) ICEV encouraged probably some people to opt for a cleaner ICEV rather than an FBEV. Undesirable synergetic effects were also observed in the Netherlands, in the 1 2 2 3 4 4 1 2 3 4 form of the existence of multiple subsidy schemes for company car users, which led them to buy electric vehicles for purely economic reasons, leading to the undesirable effect of the cars being driven primarily (80%) in fossil-fuel mode, which meant that a good deal of the money for promoting electric mobility and cleaner air was being misspent. Another important lesson is that it is indeed possible to stimulate FBEVs through a set of synergetic policies. In Norway there was strong alignment between national policies (purchase and annual tax exemption) and local policies (toll road and parking exemption), which, in combination, acted as a significant pull for FBEV adopters. Over-stimulation of FBEV leads to perverse effects, however. There is a cautionary lesson. Although demand-side measures for FBEV are key and total-cost-of-ownership of FBEV should be lower than with ICE to encourage uptake, the difference should not be too great. An imbalance in incentives may instead simply lead to extra kilometres driven and extra vehicles bought (PHEV or FBEV as an additional vehicle instead of an ICEV replacement). The case of Denmark also brings home an important lesson for policy. There is the danger of relying too much on a specific technology configuration as was the case with the battery swapping model, where only one type of vehicle was available (the Renault Fluence Z.E.). Innovation experiments with infrastructure are generally useful but not if they increase uncertainty on the consumer side too much.

Frames, agency and institutional change: the case of benchmarking in Danish construction

This study examines change and the sources influencing the formulation and diffusion of policies in construction. The change examined is the introduction of a benchmarking policy initiative in the Danish construction industry. Using institutional theory with emphasis on the concepts of frames and framings, we show how strategically motivated actors are able to frame policy problems in ways that disclose the mixture of motives, interests and institutional mechanisms at play.
in change processes. In doing so, we contribute to the literature on the role of agency in institutional change and the framing of policy problems. We conclude by highlighting how insights gained from the framing perspective present a challenge to the dominant comprehensive rationalist view of the policy process and the formulation and implementation of reform initiatives.

Framework for estimating toxic releases from the application of manure on agricultural soil: National release inventories for heavy metals in 2000-2014

Livestock manure is commonly applied on agricultural land for its fertilising properties. However, the presence of toxic substances in animal manure such as pathogens, antibiotics and heavy metals, can result in damages to ecosystems and human health. To date, although relevant for policy-making, e.g. regulation framing, their releases to agricultural land have been incompletely and inconsistently quantified at global and national scales. Here, we thus developed a generic framework for estimating such releases based on the quantities of manure applied and concentrations of toxic substances. Applying this framework, we built a global release inventory for arsenic, cadmium, chromium, copper, mercury, nickel, lead and zinc differentiated into 215 countries and 15 years (period 2000-2014). Comparisons with more narrowly-focused inventories showed overall consistency in our inventory results, although a number of uncertainties and limitations were identified. In particular, the need for harmonising sampling and analytical methods for estimating heavy metal contents in manure and generating more country-differentiated data, especially for developing countries, should be prioritised by future research studies. Using life cycle impact assessment methods, it was additionally found that mercury, zinc and copper are the substances contributing the most to the toxic impacts on human health and freshwater ecosystems resulting from manure application to land. While countries such as China, India, Russia, Brazil and the United States of America contributed to half the heavy metal releases from manure application worldwide, the impact intensity per area of agricultural land was observed to be highest for island countries, the European Union and South-East Asia because of higher per-area applications of manure. These findings demonstrate the need to perform country-specific impact assessment to support policy-making regulating the concentrations of toxic substances such as heavy metals in utilised manure.

Framework to Define Structure and Boundaries of Complex Health Intervention Systems: The ALERT Project

Health intervention systems are complex and subject to multiple variables in different phases of implementation. This constitutes a concrete challenge for the application of translational science in real life. Complex systems as health-oriented interventions call for interdisciplinary approaches with carefully defined system boundaries. Exploring individual components of such systems from different viewpoints gives a wide overview and helps to understand the elements and the relationships that drive actions and consequences within the system. In this study, we present an application and assessment of a framework with focus on systems and system boundaries of interdisciplinary projects. As an example on how to apply our framework, we analyzed ALERT [an integrated sensors and biosensors’ system (BEST) aimed at
monitoring the quality, health, and traceability of the chain of the bovine milk], a multidisciplinary and interdisciplinary project based on the application of measurable biomarkers at strategic points of the milk chain for improved food security (including safety), human, and ecosystem health (1). In fact, the European food safety framework calls for science-based support to the primary producers’ mandate for legal, scientific, and ethical responsibility in food supply. Because of its multidisciplinary and interdisciplinary approach involving human, animal, and ecosystem health, ALERT can be considered as a One Health project. Within the ALERT context, we identified the need to take into account the main actors, interactions, and relationships of stakeholders to depict a simplified skeleton of the system. The framework can provide elements to highlight how and where to improve the project development when project evaluations are required.

FTA and Innovation Systems
This special issue is one of the outputs of the 5th International Conference on Future-Oriented Technology Analysis held in Brussels 27-28 November 2014. The articles in the special issue were selected from the manuscripts presented at the conference considering their relevance for Foresight and Innovation Systems. A few additional articles have been accepted through an open ‘call for papers’ process for this special issue.

Fusion power in a future low carbon global electricity system

Fusion is one of the technologies that may contribute to a future, low carbon, global energy supply system. In this article we investigate the role that it may play under different scenarios. The global energy model ETM (originally EFDA TIMES Model) has been used to analyse the participation of fusion technologies in the global electricity system in the long term. Results show that fusion technologies penetration is higher in scenarios with stricter CO2 emissions reduction targets. In addition, investment costs and discount rates of fusion technologies are key factors for fusion implementation. Finally, the main competitors for fusion in future are Carbon Capture and Storage and fission technologies.

Future-Oriented LCA

LCA is often applied for decision-making that concerns actions reaching near or far into the future. However, traditional life cycle assessment methodology must be adjusted for the prospective and change-oriented purposes, but no standardised way of doing this has emerged yet. In this chapter some challenges are described and some learnings are derived. Many of the future-oriented LCAs published so far perform relatively short-term prediction of simple comparisons. But for more long-term time horizons foresight methods can be of help. Scenarios established by qualified experts about future technological and economic developments are indispensable in future technology assessments. The uncertainties in future-oriented LCAs are to a large extent qualitative and it is important to emphasise that LCA of future technologies will provide a set of answers and not ‘the’ answer.

Globalisation and Mainstreaming of LCA

The chapter describes how a globalised economy exacerbates the need of a mainstreaming of LCA, in particular the emergence of long, complex and geographically highly dispersed global value chains (GVCs). In documenting the three phases of the UNEP-SETAC Life Cycle Initiative, a conventional roadmap for global mainstreaming of LCA is drawn. However, the questioning by some South governments of the rationale and a North methodological bias of LCA draws attention to the significance of national and local contexts in developing countries. The chapter argues a more elaborate concept for building capacity for LCA in developing countries and suggests how to strategise national LCA agendas.
**Goal Definition**

The goal definition is the first phase of an LCA and determines the purpose of a study in detail. This chapter teaches how to perform the six aspects of a goal definition: (1) Intended applications of the results, (2) Limitations due to methodological choices, (3) Decision context and reasons for carrying out the study, (4) Target audience, (5) Comparative studies to be disclosed to the public and (6) Commissioner of the study and other influential actors. The instructions address both the conduct and reporting of a goal definition and are largely based on the ILCD guidance document (EC-JRC in European Commission—Joint Research Centre—Institute for Environment and Sustainability: International Reference Life Cycle Data System (ILCD) Handbook—General Guide for Life Cycle Assessment—Detailed Guidance. Publications Office of the European Union, Luxembourg 2010).
Empirically, this dissertation is based on four separate case studies presented in individual articles. The study of voluntary carbon market mitigation projects in the Sub-Saharan region maps out the market actors and their conceptualisations of sustainability to highlight the ideas behind market-based solutions to climate change mitigation. In examining national climate change mitigation and green growth strategies in Vietnam, it was demonstrated how the current institutional context relates to the background to long-term transformation and programmatic ideas about how to achieve it. In the study of baseline setting in developing Nationally Appropriate Mitigation Actions (NAMAs) in the building sector in Vietnam, the role of international knowledge practices in national policy-making was questioned. Finally, the examination of electricity infrastructure development showed how reforms to low-carbon energy systems are justified in two different sociotechnological settings: Mexico and Vietnam.

On the one hand, the findings indicated that over time, by invoking and appealing to arguments associated with the ideas and principles of neoliberalism climate change mitigation and low-carbon development, agendas have become more acceptable in the formation of sectoral policies. On the other hand, the analysis shows how policy experts and technocrats use their epistemic power and ideational abilities to limit the scope of debate, thus constraining the range of policy responses. When there are no fundamental transformational shifts in the background and in programmatic ideas about development, the actors that frame the institutional context within a prevailing framework further legitimise conservative ideas about climate governance. For instance, solutions normalising the temporal necessity of fossil fuels in electricity generation while justifying economic growth by means of green growth arguments become more deeply embedded in development trajectories. Narrow conceptualisations of policy problems and solutions in the cases presented here have resulted in incumbent actors resorting to quite conventional instruments of technological market-based fixes in the absence of alternative and/or more transformational visions of development.

Overall, this dissertation contributes to ongoing debates over domestic politics and policy-making regarding ‘green transformations’ and adds to the emerging policy field in developing countries contexts. It argues that there is a need to stimulate critical reflection on the existing assumptions regarding mitigation actions. It argues that governance choices, for example, in electricity infrastructure development or energy efficiency in buildings, or a broader range of mitigation actions, are not only defined by technological lockins. Equally important is the persistence of ideas that are used to justify and legitimise reforms by mobilising discourses on energy supply and security and framing energy transitions as part of wider goals to maintain socio-economic stability and pursue green growth development strategies. This dissertation shows that low-carbon development should not only be technically, institutionally and economically feasible, but also politically and ideationally feasible, to translate into action. Measures for institutionalising long-term transformation are unlikely to be effective if ideas about transformation cannot be developed within the parameters set by governance regimes.

The key argument of this dissertation is that, for the governance of low-carbon societies, it is crucial to recognise that climate change mitigation actions are more than economic or technological challenges – they are politically charged. Paying attention to problem framings and to the diversity of multi-actor perspectives could facilitate novel responses to climate change and enable more inclusive forms of governance, as well as throwing light on the fundamental incompatibility between and limited reach of generalised policy solutions and technological fixes.
affect their energy consumption by harnessing big data from real-world driving. The analysis relied on four data sources: (i) driving patterns collected from 741 drivers over a two-year period; (ii) drivers' characteristics; (iii) road type; (iv) weather conditions. The results of the analysis measure the mean ECR of BEVs at 0.183 kW h/km, underline a 34% increase in ECR and a 25% decrease in driving range in the winter with respect to the summer, and suggest the electricity tariff for BEVs to be cost efficient with respect to conventional ones. Moreover, the results of the analysis show that driving speed, acceleration and temperature have non-linear effects on the ECR, while season and precipitation level have a strong linear effect. The econometric model of the ECR of BEVs suggests that the optimal driving speed is between 45 and 56 km/h and the ideal temperature from an energy efficiency perspective is 14 °C. Clearly, the performance of BEVs highly depends on the driving environment, the driving patterns, and the weather conditions, and the findings from this study enlighten the consumers to be more informed and manufacturers to be more aware about the actual utilization of BEVs.
Heavy metals concentration and distribution in soils and vegetation at Korle Lagoon area in Accra, Ghana

The call for reclamation of land around Korle Lagoon in Accra, Ghana, where burning of E-waste and cultivation of vegetables takes place, make risk assessment of heavy metal contaminations important. This study aimed at evaluating the levels and risk of heavy metal contamination in soils and vegetation around the Korle lagoon area in Accra.

Geoaccumulation index, enrichment factor and pollution load index were determined to assess the risk of contamination. The levels and distribution of nine heavy metals (Pb, Hg, Cd, As, Zn, Sn, Ni, Cu and Cr) in soil (0 – 20 cm) and common vegetation (Panicum maximum, Imperata cylindrica, Lactuca sativa and Hibiscus sabdariffa) from the area using Atomic Absorption Spectrometer (AAS) were assessed. The area was divided into five sites namely; the e-waste site (S1), gardens area (S2), recreational area (S3), reclaimed area (S4) estuary (S5), and the control (S6) which was about 700 m away. Soil analysis showed that the concentration of Pb (184.44 mg/kg), Cd (103.66 mg/kg), Cu (202.99 mg/kg), Ni (72.00 mg/kg) and Sn (705.32 mg/kg) at S1 exceeded their WHO/FAO thresholds for agricultural soils. Concentrations of heavy metals in soils from the e-waste site was significantly different (p < 0.01) from the other sites. High accumulations of heavy metals were also observed in the plants samples collected from the study sites, with the concentrations of Cu, Pb, Ni and Cd exceeding their acceptable limits. Laws against open burning of e-waste should be enforced and animals should be restricted from grazing on the forage.

High Speed Rail: Implications for carbon emissions and biodiversity

Rail has traditionally been seen as ‘good’ for the environment, as it is fast and efficient with a low carbon footprint. With respect to HS2 in the UK, new environmental debates have arisen over the competing global objectives of reducing the carbon footprint of HSR and the need to maintain and enhance local biodiversity and habitat. This paper identifies, measures and comments on the longer term environmental consequences of major infrastructure decisions that have to be made today. Short term pragmatism is seen as the means by which these decisions are made, and this results in issues relating to the complexity and uncertainty in assessing future impacts being relegated to a secondary level of importance. Mitigation measures (and not alternative routes) are discussed, and the legacy value of HSR to future generations is based on notions of short term mobility and economic growth, and not on the lower levels of carbon emissions and biodiversity loss.

High-throughput migration modelling for estimating exposure to chemicals in food packaging in screening and prioritization tools

Specialty software and simplified models are often used to estimate migration of potentially toxic chemicals from packaging into food. Current models, however, are not suitable for emerging applications in decision-support tools, e.g. in Life Cycle Assessment and risk-based screening and prioritization, which require rapid computation of accurate estimates for diverse scenarios. To fulfil this need, we develop an accurate and rapid (high-throughput) model that estimates the fraction of organic chemicals migrating from polymeric packaging materials into foods. Several hundred step-wise simulations optimised the model coefficients to cover a range of user-defined scenarios (e.g. temperature). The developed model, operationalised in a spreadsheet for future dissemination, nearly instantaneously estimates chemical migration, and has improved performance over commonly used model simplifications. When using measured diffusion coefficients the model accurately predicted ($R^2 = 0.9$, standard error (Se) = 0.5) hundreds of empirical data points for various scenarios. Diffusion coefficient modelling, which determines the speed of chemical transfer from package to food, was a major contributor to uncertainty and dramatically decreased model performance ($R^2 = 0.4$, Se = 1). In all, this study provides a rapid migration modelling approach to estimate exposure to chemicals in food packaging for emerging
screening and prioritization approaches.

Home-end and activity-end preferences for access to and egress from train stations in the Copenhagen region

Increasing public transport use with the aim of improving the sustainability of cities should focus not only on enhancing level and quality of the service offered, but also on understanding determinants of the choice of access and egress modes to and from the railway network. This study analyzes the difference in preferences at the home-end and activity-end for travelers who have chosen train as their main travel mode while investigating the effect of policy variables such as car parking availability, bicycle parking availability and type, and bicycle on train possibility. Specifically, this study analyzes the choices between five transport modes (i.e., “walk,” “bicycle,” “car driver,” “car passenger,” “bus”) for 2921 home-end and 3658 activity-end trips. Joint mixed logit models are specified and estimated to account for heteroscedasticity and correlation across alternative modes as well as taste heterogeneity across travelers. Model estimates and pseudo-elasticities uncover the importance of travel time and underline how the improvement of walkability, bikeability, and bus service would contribute significantly to the increase in the probability of choosing sustainable modes to and from train stations. Moreover, model results emphasize the role of bicycle parking in terms of the sheer number of spaces to be increased as well as covered places to be offered at the activity end, de facto giving the possibility to leave a bicycle at that end during the night. Lastly, model results show that it is a matter of not only time and trip characteristics, but also traveler characteristics, occupation, and purpose.

Household electricity consumers' incentive to choose dynamic pricing under different taxation schemes: Electricity consumers' incentive to choose dynamic pricing

Dynamic pricing of retail electricity, as opposed to the widely applied average pricing, has often been proposed to enhance economic efficiency through demand response. The development of variable production from renewable energies and expectations about the installation of heat pumps and electric vehicles has now reinforced interest in flexible demand and dynamic pricing. With a roll-out of smart metering one important technical hurdle is going to be cleared, and dynamic retail pricing may soon become an eligible option for many households. We quantify the potential incentives to adopt new pricing schemes using exemplary Danish data. Until now, limited activity of household consumers on retail markets indicates that switching supplier or contract is perceived costly. We apply the concept of switching costs to explain this hesitant behavior, and use it to estimate a threshold level based on recent observations in the Danish market. We calculate potential savings from dynamic pricing and show how the choice of electricity taxation technique may hamper or enhance potential benefits. In the light of switching costs, our results suggest that the combination of smart meter roll-out and dynamic pricing offerings might be insufficient to convince the majority of households to switch contracts and become active in response to prices, unless they hold a substantial flexibility potential. Dynamic taxation, even if applied to parts of the levies, could contribute significantly to inducing flexible consumption.

Households' hourly electricity consumption and peak demand in Denmark

The electrification of residential energy demand for heating and transportation is expected to increase peak load and require additional generation and transmission capacities. Electrification also provides an opportunity to increase demand response. With a focus on household electricity consumption, we analyse the contribution of appliances and new services, such as individual heat pumps and electric vehicles, to peak consumption and the need for demand response incentives to reduce the peak. Initially, the paper presents a new model that represents the hourly electricity consumption profile of households in Denmark. The model considers hourly consumption profiles for different household appliances and their contribution to annual household electricity consumption. When applying the model to an official scenario for annual electricity consumption, assuming non-flexible consumption due to a considerable introduction of electric vehicles and individual heat pumps, household consumption is expected to increase considerably, especially peak hour consumption is expected to increase. Next, the paper presents results from a new experiment where household customers are given economic and/or environmental incentives to shift consumption to or away from specified hours. The experiment focuses on the present classic consumption and shows that household customers do react to incentives, but today the flexibility of the classic consumption is limited. Considering electric vehicles and individual heat pumps, for an individual household, the consumption of each of these technologies roughly doubles the household's consumption and considerably increases their potential for flexibility. Thus, in order to introduce incentives for demand flexibility, while considering reducing peak consumption, policy makers should initially focus on households that have a heat pump and/or an electric vehicle.

How Daily Operational Meetings Can Support Transformation To A Lean Improvement Culture

With pressure for creating more value with fewer resources, many organizations pursue becoming Lean. However, many are unsuccessful in the transformation necessary for sustainable change, such as creating an improvement culture. This study investigates how operational meetings, offering frequent touch points, can be used to intentionally support cultural transformation. An explorative case study identified more than 30 types of meeting activities in five categories: Information, Action, Sparring, Learning, and Relational. A comparative case study then investigated meeting set-ups and their role in supporting cultural change. The analysis shows how meeting set-ups can be designed to support cultural transformation.

How indicative is a self-reported driving behaviour profile of police registered traffic law offences?

Although most motorised countries have experienced massive improvements in road safety over the last decades, human behaviour and differences in accident risk across sub-groups of drivers remains a key issue in the area of road safety. The identification of risk groups requires the identification of reliable predictors of safe or unsafe driving behaviour. Given this background, the aim of this study was to test whether driver sub-groups identified based on self-reported driving behaviour and skill differed in registered traffic offences and accidents, and whether group membership was predictive of having traffic law offences. Sub-groups of drivers were identified based on the Driver Behaviour Questionnaire (DBQ) and the Driver Skill Inventory (DSI), while traffic offences and accidents were register-based (Statistics Denmark). The participants (N = 3683) were aged 18–84 years and randomly selected from the Danish Driving License Register. Results show that the driver sub-groups differed significantly in registered traffic offences but not in registered accidents. In a logistic regression analysis, the sub-group "Violating unsafe drivers" was found predictive of having a traffic offence, even when socio-demographic variables and exposure were controlled for. The most important predictive factor, however, was having a criminal record for non-traffic offences, while gender, living without a partner, and being self-employed also had a significant effect. The study confirms the use of the DBQ and DSI as suitable instruments for predicting traffic offences while also confirming previous results on accumulation of problematic behaviours across life contexts. The finding that driver sub-groups did not differ in registered accidents supports the recent research activities in finding and modelling surrogate safety measures.

How is it going? Performance assessment in major projects

Determining the performance of a major project is a challenge for both practitioners and scholars. In the context of operational change projects the challenge is exacerbated by the service-intensive nature of the transformation, temporal disconnects between contracting and delivery and lack of appropriate metrics. This paper considers performance from a service delivery perspective. Current measures of performance were noted to be inadequate in practice. The service operations literature provided frameworks which were investigated for their utility and supplemented by qualitative data to generate an enhanced service performance model. This was then tested using a survey and a structural equation model derived. Development of this yielded new classifications but most importantly, provided a more meaningful method for measuring the performance of operational transformation projects. Specifically, it is shown that expectations and perceptions are measured on different scales, and that quality performance is inseparable from other performance aspects. The contributions of this paper are to address an important practical problem but also to contribute to the development of the discussion of performance management in major projects from an OM perspective.

How Malaysian managers persuade employees’ innovative behaviour?

The intention of this paper was to examine the impact of six selected leaders’ behaviours on employees’ innovative behaviour through the mediating role of leader-member exchange (LMX). A total number of 155 pairs of employees and their immediate managers participated in this study. Employees rated their managers’ behaviours and managers evaluated their subordinates’ innovative behaviour. Both managers and employees answered to LMX measurement. Then, the agreements of employees’ and managers’ LMX rating were applied based on the results of within and between analysis (WABA). The obtained data were analysed through structural equation modelling-partial least square (SEM-PLS). The findings revealed the significance of mediating role of LMX in relationship between behaviour of recognising, taking risks for change and paternalistic with employees’ innovative behaviour. Thus, this study has contributed to the leadership literature in addition to providing a clear vision for Malaysian managers to increase employees’ innovative behaviour via improving exchange relationship.
How many EMA-workshops are needed to collect a representative sample of events in a hospital ward?

The effect modifier assessment (EMA) method (Edwards & Winkel, 2016) is a method for assessing the impact of an intervention and modifiers on a desired outcome e.g. improved work environment. The EMA-method captures events (a change in work) in a ward and for each event assess 1) impact on work environment and 2) if the event was part of the intervention or not. The EMA-method rely on the EMA-workshop – a structured group interview method inspired by the chronicle workshop (Limborg & Hvenegaard, 2011) to collect data. However, healthcare organizations are complex and staff carry out many different and diverse tasks. This poses a problem when using the EMA-method and raises the research question of this abstract: How many EMA-workshops are needed to generate a representative collection of events in a ward? Methods Six EMA-workshops each with a full surgical team of six people was conducted in a heart surgery ward with 150 employees (Edwards & Teeves, 2015). The collected events from all workshops was analyzed and grouped into themes. Data was considered representative when the next workshop did not produce any new themes (saturation). Results In the test case, most if not all employees focused on surgery. The ward was organized in three specialties: Heart surgery, Lung surgery and Child heart surgery. Events differed between specialties and therefor it was expected that saturation would be reached after minimum three workshops. The heart center is comparable to other surgical units and will exhibit a lower degree of variation in work tasks and processes than a medical ward. The general recommendation is that each EMA-workshop include participants from all relevant occupational groups for a specialization. A specialization should be understood broadly as they may not be formally defined but have developed over time e.g. a specific patient group. The number of needed EMA-workshops depend on the number of specializations and researchers should uncover the extent and number of specializations before deciding the number of workshops. The number of EMA-workshops is recommended to be at least equal to the number of specialties relevant to the study.

How the reverse supply chain contributes to a firm’s competitive strategy: a strategic alignment perspective

The ongoing transition to a Circular Economy is changing the shape of Supply Chains. They are becoming more ‘Closed-Loop’, combining forward and reverse flows of products and materials. Reverse Supply Chains (RSCs), originally considered as a solution for handling waste or recovering residual value, can play a pivotal role in determining the competitive advantage of the firm. Firms do not always exploit the potential of the RSC, and the conditions allowing exploitation remain unclear. This paper explores the alignment between the RSC and the competitive strategy of the firm. Results from seven case studies, focusing on original equipment manufacturers (OEMs), show how the RSC can play a strategic, tactical, or operational role for the firm. The paper applies for the first time the concept of strategic alignment to the RSC and practitioners can use the proposed framework to analyse the role of the RSC within their firm.
How the reverse supply chain impacts the financial performance of original equipment manufacturers

This thesis examines the financial impact of a firm's reverse supply chain (RSC). Specifically, the thesis examines the two questions of how the RSC can contribute to the financial performance of the firm and which factors are decisive for the RSC's financial contribution. The thesis focuses on original equipment manufacturers. The thesis results show that the
RSC can contribute to the financial performance of the firm in more than 20 different ways, which the thesis defines as functions of the RSC. Examples of RSC-functions are 1) resale of recovered end-products to price-focused market segments in the firm’s primary markets, 2) resale to customers in new markets (in e.g. emerging economies), and 3) sale of used materials back to the firm’s original material suppliers. The firm’s RSC can conduct several RSC-functions simultaneously and the financial benefits from operating these RSC-functions differ widely among functions. The factors that are decisive for the RSC’s financial contribution depend on the type of RSC-function. For a RSC-function that recovers and resells end-products examples of factors decisive the function’s financial contribution are 1) the market’s willingness to pay for recovered products, 2) the firm’s profits from servicing recovered products once sold, and 3) the added probability of selling additional products to customers of recovered products. The thesis demonstrates that manufacturers can achieve considerable financial contributions from the RSC, which contracts the traditional perception of the RSC in academic literature as well as with logistics practitioners.
How to Identify Possible Applications of Product Configuration Systems in Engineer-to-Order Companies

Product configuration systems (PCS) play an essential role when providing customised and engineered products efficiently. Literature in the field describes numerous strategies to develop PCS but neglects to identify different application areas. This topic is particularly important for engineer-to-order (ETO) companies that support gradual implementation of PCS due to large product variety and, several times, higher complexity of products and processes. The overall PCS process can thereby be broken down, and the risk minimised. This paper provides a three-step framework to identify different applications of PCS including the following steps: (1) identifying potential PCS, (2) aligning IT development, and (3) establishing an overview of PCS application. The study is supplemented by results from a case study in which the proposed framework was tested. The results from the testing confirm that the framework is applicable, as it leads to strategic and smart decisions regarding the implementation of PCS.

How to Use SVMAs to Reduce the Carbon Pricing and Climate Finance Gap: Numerical Illustrations

A temporary gap is generated by the difference between the Social Value of Mitigation Activities (SVMAs) and implementable carbon prices. A spectrum of options are available to handle this. These options encompass policy instruments that give different weights to ‘command and control’ measures and to economic incentives. We analyze here how to combine an explicit carbon price that rewards mitigation activities every year and a notional price embedded in devices that reward low carbon investments beforehand through lowering their risk-weighted capital costs. The latter option is essential in order to hedge against two uncertainties that adversely affect technologies having high capital costs. The first relates to technologies which are at the beginning or mid-way of their experience curve. The second relates to the net signal launched by explicit carbon prices given the presence of noises that swamp it.

We first illustrate, based on five case studies, the equivalence curves between carbon prices and percentages of reduction of capital costs. We argue then that a notional price equal to the SVMA can maximize the economic efficiency of financial devices that reduce the capital costs of a low carbon project and we discuss the necessity of a world SVMA and of national SVMAs. We then introduce uncertainty in the analysis and show that contingent risks theoretically need carbon prices to grow to a level well beyond their political acceptability. Reducing the risk-weighted capital costs and rewarding upfront low-carbon investments at the present value of the SVMA is an efficient way of overcoming these barriers. Finally, we show, in the case of India, how to assess a national SVMA that includes the climate benefits and the development co-benefits of mitigation activities.

We then discuss how to articulate a World SVMA (paragraph 108 of the Paris Decision), national SVMAs and explicit carbon prices (in line with NDCs) to bridge the funding gap, tackle the ‘100G$ and +’ issue, and maximize the gains of cooperation around climate policies.

Human health no-effect levels of TiO2 nanoparticles as a function of their primary size

As engineered nanomaterials are increasingly introduced on the market into a broad range of commodities or nanoproducts, there is a need for operational, reliable tool, enabling to consistently assess the risks and impacts associated with the releases of nanoparticles. The lack of a developed metric that accurately represents their toxic effects while capturing the influence of the most relevant physicochemical properties is one of the major impediments. Here, we investigate the relationships between the toxic responses of nano-sized and micro-sized particles in in vivo toxicological studies and their physicochemical properties. Our results for TiO2 particles indicate statistically significant associations between the primary particle size and their toxicity responses for combined inhalation and ingestion exposure routes, although the numerical values should be considered with care due to the inability to encompass influences from other relevant physicochemical properties like surface coatings. These findings allow for expressing mass-based adverse effect levels as a continuous function of the primary size of particles. This meaningful, exploratory metric can thus be used for screening purposes and pave the way for reaching adaptive, robust risk assessments of nanomaterials, e.g. for setting up consistent threshold levels, as well as consistent life cycle assessments of nanoproducts. We provide examples of such applications.

Hvordan kan man arbejde med shared space i kommuner?
At flere og flere over hele verden flytter fra landet og til byerne er efterhånden et ret velkendt fænomen, og de større bysamfund kommer da også med mange
fordele så som mindre transport behov og kortere afstande mellem faciliteter bare for at nævne nogle. Den øgede befolkningsmængde resulterer dog også i en række udfordringer for byerne og kommunerne i forhold til at sørge for tilstrækkelige faciliteter til at understøtte livet og dagligdagen for de mange borgerere, så som børnepasning, skoler, sports faciliteter, kulturfaciliteter, boliger og så videre. Så i takt med befolkningstilvæksten vil der altså oftest også komme
et øget behov for plads som kan være svært at imødekomme. Det er her hvor shared space – det at dele lokaler og bygninger mellem forskellige grupper eller organisationer – kan spille en rolle.

**Hybrid choice model to disentangle the effect of awareness from attitudes: Application test of soft measures in medium size city**
The need to reduce private vehicle use has led to the development of soft measures aimed at re-educating car users through information processes that raise their awareness about the benefits of environmentally friendly modes, encouraging them to voluntarily change their travel choice behaviour (level of services characteristics being equal). It has been observed that these measures can produce enduring changes, being the result of mindful decisions. It is important then to try and understand what contributes to shape individuals’ preferences in order to be able to define the best policy for fostering changes toward more pro-environmental modes. The objective of this work is to provide empirical evidence of the effect of awareness and individual attitudes on the switch from car driver to more sustainable modes such as Park and Ride. In particular we attempt to discriminate the effect of awareness due to the information provided in a Stated Preference experiment from the effect of individuals’ attitudes toward stress and social norms with respect to sustainable transport modes. The case study refers to the implementation of a Voluntary Travel Behaviour Change programme in Cagliari (Italy), carried out with the purpose of promoting the use of the light rail in Park and Ride mode. To account for all these effects in the choice between car and Park and Ride we estimate a Hybrid Choice Model where the discrete choice structure allows us to estimate the effect of awareness of environment and stress, while the latent structure allows us to estimate the effect of the latent effect of norms and attitudes toward environment and stress. The results from this case study show that the more people consider the information about stress useful, the more they tend to behave sustainably, suggesting the importance of reporting feedback about stress in the personalised travel plan to promote sustainable mobility. Interestingly, the information about pollution has instead less impact in shifting behaviour toward sustainable modes.

Identification of critical technology building blocks

In order to have a better base for decisions, R&D managers need to know what the critical areas of development are in relation to the technologies they develop, mature, and include in the portfolio. As most of the technologies in a company have the potential to have a significant impact on competition, the challenge is to know how to identify and prioritize the development tasks. If possible, an effective strategy can be defined. This article suggests a framework for identification and analysis of a product portfolio, with special emphasis on identifying critical technology building blocks based on reasoning about product properties. Current approaches lack such views, and by focusing on these, potential make or break decisions are better supported. It is suggested to adopt the proposed framework to clarify where in the portfolio the technology needs critical attention for the next development steps. The framework is based on methods and theories in literature. The analysis of the portfolio is carried out through the framework in three steps: by creating an overview of the portfolio encompassing product and technology, assessing the elements in the overview with assessment metrics, and using property chains to identify critical technology building blocks.

Identification of Excess Heat Utilisation Potential using GIS: Analysis of Case Studies for Denmark

Excess heat is present in many sectors, such as the industry and utility. The utilization of these heat sources could reduce the primary energy consumption and thus reduce carbon dioxide emissions. This work presents the results of a geographical mapping of excess heat, in which excess heat from the industry and utility sector is distributed to specific geographical locations in Denmark. Based on this mapping, a systematic approach for identifying cases for the utilization of excess heat is proposed, considering district heating, process heat and power generation. The technical and economic feasibility of using this approach is evaluated for four scenarios. Special focus is placed on the challenges for the connection of excess heat sources to heat consumers, as well as tax schemes applicable in Denmark. To account for uncertainties in the model input, Monte Carlo simulations and Morris Screenings are performed to determine the standard deviation of the results and to determine the most important model parameters. The presented method shows how the geographical mapping of excess heat sources can be used to identify its utilization potentials. In combination with the economic model, a fast evaluation and comparison of the feasibility of different matches can be performed. The evaluation of the identified case studies shows that it is economically feasible to connect the heat source to the public energy network or use the heat to generate electricity. However, the uncertainty analysis suggests that the results can only be indicative and are useful for a fast evaluation and comparison of different matches.

Identifying and Managing Engineering Design Requirements for Emerging Markets

In the last decade, emerging markets have become a significant force in the world economy. It has become increasingly important for global manufacturing companies to develop products for emerging markets, which appropriately address local needs and requirements. Therefore, it is necessary, especially for those companies originally from developed markets, to acquire an in-depth understanding of particular design requirements in emerging markets in order to adapt both company products and approaches in such contexts.

Prior studies on the identification and management of design requirements have predominantly been conducted in the context of developed countries and relatively affluent markets. Emerging markets are distinct from developed markets in terms of numerous contextual factors, e.g., regulatory environments and competitive landscapes. These factors influence the requirement identification and can lead to changes in design requirements. However, the influence of these factors have not been explicitly studied in the context of emerging markets. In addition, current studies on design requirements
focus on user requirements, whereas requirements from other perspectives have received limited attention. There is a need for an overview of different perspectives in requirement identification for manufacturing companies and their corresponding assessments in the context of emerging markets.

Therefore, this research project is motivated to 1) investigate the process of identifying and managing design requirements for emerging markets, with the purpose of examining the challenges and gaps in developed-market companies’ current practice and; 2) support companies in identifying design requirements for emerging markets with an efficient approach. This research project has been performed as a close collaboration between academy and industry. Two empirical studies have been conducted with Danish and Chinese manufacturing companies employing survey and case study as research methods. These two studies demonstrate that for a developed-market company, to identify design requirements is more challenging for emerging markets than that for home markets. The key findings suggest that the process of identifying and managing design requirements, which usually apply to developed markets, should be adapted for emerging markets. In such adaptions, particular attention should be paid to 1) understanding competitions and regulations in target markets, 2) selecting appropriate sources to gather information, and 3) being flexible in reacting to the dynamic and complex emerging-market context.

Based on the findings, the Perspective-oriented Requirement Excellence toolkit has been developed to support companies with the preparation and planning of requirement identification, especially for unfamiliar markets. This toolkit provides a structured framework to organise design requirements, which supports the identification of gaps in the existing requirement set, and assists the communication of design requirements between different stakeholders. It also provides a systematic approach to plan the process for identifying design requirements, which improves the efficiency in terms of utilising expertise and allocating resources. The toolkit has been evaluated at a workshop, which demonstrates the value of this method in supporting a real case practice.

This project has been conducted as interdisciplinary research. It supplements with a theoretical contribution to requirement engineering and engineering design, which in this case is an advanced understanding of the perspectives considered in requirement identification, and co-evolution of design requirements and product development processes in emerging markets. It also contributes to innovation management with implications that support managers in planning process, and allocating resources to identifying and managing design requirements in product development projects that target at emerging markets.

Identifying product development crises: The potential of adaptive heuristics
This paper introduces adaptive heuristics as a tool to identify crises in design projects and highlights potential applications of these heuristics as decision support tool for crisis identification. Crises may emerge slowly or suddenly, and often have ambiguous signals. Thus the identification of a project crisis is often difficult. Yet, to allow fast crisis response, timely identification is critical for successful crisis management. Adaptive heuristics are judgement strategies that can strive in circumstances of limited and ambiguous information. This article presents a theoretical proposition for the application of heuristics in design sciences. To achieve this, the paper compares crises to ‘business as usual’, and presents sixteen indicators for emerging crises. These indicators are potential cues for adaptive heuristics. Specifically three adaptive heuristics, One-single-cue, Fast-and-Frugal-Trees, and Tallying, are well suited to support design practitioners to make robust inferences about the situation. The paper presents potential applications of these three heuristics and provides an outlook on further research on adaptive heuristics in design sciences.

Illustrative Case Study: Life Cycle Assessment of Four Window Alternatives

This report serves as an example report on how to perform an LCA according to the guidance given in Chap. 37 and how to structure the report according to the reporting template in Chap. 38. The goals of the LCA were (i) to perform a benchmarking of a prototype wood/composite (W/C) window made out of glass fibre against three alternative window types currently offered in the market (made of wood (W), wood/aluminium (W/ALU), and PVC) and (ii) to identify environmental hotspots for each window system.

Impact of product configuration systems on product profitability and costing accuracy

This article aims at analyzing the impact of implementing a product configuration system (PCS) on the increased accuracy of the cost calculations and the increased profitability of the products. Companies that have implemented PCSs have achieved substantial benefits in terms of being more in control of their product assortment, making the right decisions in the sales phase and increasing sales of optimal products. These benefits should have an impact on the company's ability to make more accurate cost estimations in the sales phase, which can positively affect the products' profitability. However, previous studies have not addressed this relationship to a great extent. For that reason, a configure-to-order (CTO) manufacturing company was analyzed. A longitudinal field study was performed in which the accuracy of the cost calculations and the products' profitability were analyzed before and after a PCS was implemented. The comparison in the case study revealed that increased accuracy of the cost calculations in the sales phase and consequently increased profitability can be achieved by implementing a PCS.

Impacts of offshore grid developments in the North Sea region on market values by 2050: How will offshore wind farms and transmission lines pay?

Increasing the integration of renewable energy in Northern and Central Europe markets is greatly influenced by the development of electricity transmission grid infrastructure. On the background of the fast development of offshore wind energy and its connection to the onshore electricity systems, a coordinated grid development in the North Sea may not
only save costs for individual wind farms, but also deliver additional benefits through the provision of increased interconnection of electricity markets. The previous studies do not include offshore wind development with high ambition in the long term perspective and do not focus on the assessment of the specific effects on the economic value of offshore wind farms connected to Belgium, Norway the UK, the Netherlands, and Germany (North Sea Link, Cobra Cable, Viking Link, Nord Link, BritNed and Nemo Link). This paper tries to shed some lights on the substantial differences in the expected economic exposure of wind power plants and transmission lines to the development of the electricity grid in the North Sea. Since details of the prospective energy system around the North Sea region shape these revenue expectations, we further develop and apply the energy model Balmorl. The tool is used to quantify effects of the implementation of a meshed offshore grid compared to a radial grid that connects wind farms in a non-coordinated fashion to the countries by 2050. The model runs conducted for the present paper show substantial variation of expectable market values of wind farms on hub level due to impacts of different options for grid structures. The results aim to inform the discussion on possibilities for the allocation of grid expansion costs to the different connected countries including Belgium, Denmark, Germany, the Netherlands, Norway and Britain.

Implementation of preventive interventions – what are the contextual co-players and opponents?
Statement of the problem
Preventive interventions aims at improving the psychosocial work environment within organizations. The nature of preventive interventions are therefore that it affects the context in which it is implemented. We will claim that the context also affects the implementation of the intervention. When the context affects the intervention the current approach is to consider to which extent the intervention program was followed (implementation fidelity, (Carroll et al., 2007)). Implementation fidelity implies two underlying logics, one that intervention models always are applicable, and two that the model is implemented in a static organization (Gish, Poulsen, & Ipsen, 2014; K. Nielsen, 2013). Implementation fidelity does not explain which organizational and managerial circumstances that affected the intervention positively or negatively. Thus, we find studies that show intervention models work, but the studies cannot explain why the intervention models work. Realistic evaluation has been suggested as an approach to gain information about which circumstances have affected who, and under which conditions (Hasle, Kvorning, Rasmussen, Smith, & Flyvholm, 2012; K. Nielsen, Abildgaard, & Daniels, 2014; Starheim, 2014).

When investigating the effects of interventions, it remains unclear which conditions have influenced the implementation process. The initial conditions suggested as important for the implementation process is among others management support (Cox et al., 2000; Kompier, Geurts, Grunemann, Vink, & Smulders, 1998). Others have also pointed to the importance of employee involvement (Lamontagne, Keegel, Louie, Ostry, & Landsbergis, 2007; Karina Nielsen, Randall, Holten, & Gonzalez, 2010). However, the studies do not explain the causal relation behind. Qualitative studies find that the term management support is too broad a term, because support from both top management and the first line manager is crucial for the implementation process (Ipsen, Gish, & Poulsen, 2014; K. Nielsen, 2013). The general recommendation about employee involvement in interventions is criticized because it is not specified whether the involvement should be of all employees during the entire process, or it should just be involvement of few employees in one intervention step. (K. Nielsen, 2013). Generally, we know much about the criteria for initiating an intervention, but we need more knowledge about how implementation actually happens. This paper investigates the promoting and inhibiting factors when implementing a preventive intervention. The majority of studies investigating promoting and inhibiting factors in relation to implementation success primarily focus on the promoting factors. Inhibiting factors are lack of time for the
intervention, change history in the organization, and that the intervention goals are not linked to the company's KPIs (Ipsen et al., 2014). Some of the promoting factors will inevitably be inhibiting when they are absent, but we do not know how lack of management support manifest itself.

**Procedures** In Denmark the worksites within hospitals is managed by five regions. The Capital Region of Denmark employs 36000 people, who primarily work within healthcare. The worksites are primarily hospitals, but there are also residential accommodation and pharmacies. All capital worksites fill out an employee satisfaction survey every third year. When the results from the survey is announced, the worksites should identify target areas and hereafter initiatives to the target areas. We have identified the worksites where there has been a positive development in the psychosocial work environment from the employee satisfaction survey in 2011 to the survey in 2014. We choose four worksites, where we do interviews with the managers and facilitate a chronicle workshop (Limborg & Hvenegaard, 2011; Poulsen, Ipsen, & Gish, 2014) with employees. The interviews seeks to investigate which initiatives was launched as a reaction to the employee satisfaction survey in 2011, and the chronicle workshop investigates whether the initiatives was actually implemented in the daily work routines, and whether other circumstances could have influenced the employee satisfaction survey in 2014.
Improving Healthcare Logistics Processes

Healthcare costs are increasing due to an ageing population and more sophisticated technologies and treatments. At the same time, patients expect high quality care at an affordable cost. The healthcare industry has therefore experienced increasing pressures to reduce the cost of healthcare provision whilst providing high quality care. Logistics activities in hospitals provide a significant opportunity for cost containment in healthcare through the implementation of best practices.

Literature provides little guidance on how to improve healthcare logistics processes. This study investigates logistics processes in hospitals and aims to provide theoretically and empirically based evidence for improving these processes to both expand the knowledge base of healthcare logistics and provide a decision tool for hospital logistics managers to improve their processes.

Case studies were conducted at hospitals in Denmark and the US investigating three different types of processes: bed logistics, hospital cleaning, and pharmaceutical distribution. Based on an analysis and comparison of the case studies, a set of factors were identified influencing the decision on how to improve healthcare logistics processes. Furthermore, a method for benchmarking healthcare logistics processes was developed. Finally, a theoretically and empirically founded framework was developed to support managers in making an informed decision on how to improve healthcare logistics processes.
This study contributes to the limited literature concerned with the improvement of logistics processes in hospitals. Furthermore, the developed framework provides guidance for logistics managers in hospitals on how to improve their processes given the circumstances in which they operate.

Improving substance information in usetox®, part 1: discussion on data and approaches for estimating freshwater ecotoxicity effect factors
The scientific consensus model USEtox® is recommended by the European Commission as the reference model to characterize life cycle chemical emissions in terms of their potential human toxicity and freshwater aquatic ecotoxicity impacts in the context of the International Reference Life Cycle Data System (ILCD) Handbook and the Environmental Footprint pilot phase looking at products (PEF) and organisations (OEF). Consequently, this model has been systematically used within the PEF/OEF pilot phase by 25 EU industry sectors, which manufacture a wide variety of consumer products. This testing phase has raised some questions regarding the derivation of and the data used for the chemical-specific freshwater ecotoxicity effect factor in USEtox®. For calculating the potential freshwater aquatic ecotoxicity impacts, USEtox® bases the effect factor on the chronic hazard concentration (HC50) value for a chemical calculated as the arithmetic mean of all logarithmized geometric means of species-specific chronic lethal (or effect) concentrations (L(E)C50). We investigated the dependency of the USEtox® effect factor on the selection of ecotoxicological data source and toxicological endpoints, and we found that both influence the ecotoxicity ranking of chemicals and may hence influence the conclusions of a PEF/OEF study. We furthermore compared the average measure (HC50) to other types of ecotoxicity effect indicators like the lowest species EC50 or NOEC, frequently used in regulatory risk assessment, and demonstrated how they may also influence the ecotoxicity ranking of chemicals. We acknowledge that these indicators represent different aspects of a chemical's ecotoxicity potential and discuss their pros and cons for a comparative chemical assessment as performed in LCA and in particular within the PEF/OEF context. Improving substance information in usetox®, part 2: Data for estimating fate and ecosystem exposure factors

The scientific consensus model USEtox® is developed since 2003 under the auspices of the UNEP-SETAC Life Cycle Initiative as a harmonized approach for characterizing human and freshwater toxicity in life cycle assessment (LCA) and other comparative assessment frameworks. Using physicochemical substance properties, USEtox® quantifies potential human toxicity and freshwater ecotoxicity impacts by combining environmental fate, exposure and toxicity effects information, considering multimedia fate and multi-pathway exposure processes. The main source to obtain substance properties for USEtox® 1.01 and 2.0 is the Estimation Program Interface (EPI SuiteTM ) from the U.S. Environmental Protection Agency. However, since the development of the original USEtox® substance databases, new chemical regulations have been enforced in Europe such as the REACH and the Plant Protection Products regulations. These regulations require that a chemical risk assessment for humans and the environment is performed before a chemical is placed on the European market. Consequently, additional physicochemical property data and new toxicological end-points are now available for thousands of chemical substances. The aim of the present study is to explore to which extent the new available data can be used as input for USEtox® - especially for application in Environmental Footprint studies - and to discuss how this would influence the quantification of fate and exposure factors. Initial results show that the choice of data source and the parameters selected can greatly influence fate and exposure factors leading to potentially different rankings and relative contributions of substances to overall human toxicity and ecotoxicity impacts. Moreover, it is crucial to discuss the relevance of exposure factor for freshwater ecotoxicity impacts particularly for persistent highly adsorbing and bio-accumulating substances. Including product features in process redesign

This article suggests a visual modelling method for integrating models of product features with business process models for redesigning the business processes involving specifications of customer-tailored products and services. The current methods for redesigning these types of business processes do not take into account how the product features are applied throughout the process, which makes it difficult to obtain a comprehensive understanding of the activities in the processes and to generate significant improvements. The suggested approach models the product family using the so-called product variant master and the business process modelling notation for modelling the process flow. The product model is combined with the process map by identifying features used in each step of the process flow. Additionally, based on the information absorbed from the integrated model, the value stream mapping modelling technique is applied to the specification process to evaluate its performance in quantifiable terms. The proposed modelling approach was investigated through three case studies. Experiences from the case studies were that the suggested modelling techniques gave additional insight into the specification processes and formed a good basis for process improvement. Furthermore, the case studies indicated that the suggested modelling techniques were applicable and easy to use.

Inclusive planning in transport and energy STI-policies

Transition to a more sustainable and fossil-free energy system is of global interest, and implies social challenges for the developed world including the European Union. In particular, the energy consumption related to transport constitutes a
significant challenge. If not serious changes are made the transport sector can lead to more than a doubling of CO2 emissions by 2050 (Edenhofer et al., 2014). Transport in this context includes transport of both people and goods, and it includes transport on land, sea and air. Responsible research and innovation should take into account this large social challenge of securing a more sustainable and fossil-free energy system. Furthermore, responsible research and innovation should take into account both the required changes in all citizens’ daily life due to this transition as well as the driving force of grassroots innovation movements.

Increased accuracy of cost-estimation using product configuration systems
This article describes an approach for utilizing Product Configuration Systems (PCS) for quantifying project costs in project-based companies. It presents a case study demonstrating a method of quantifying costs in a way that makes it possible to configure cost- and time estimates. Piecework costs, material costs and sub-supplier costs are used as principle cost elements and linked to structural and process elements to facilitate configuration. The cost data are used by the PCS to generate fast and accurate cost-estimates, quotations, time estimates and cost summaries. The described cost quantification principles have been used in a Scandinavian SME (Small and Medium-sized Enterprise) since the 90’s, but have since 2011 been adopted to be used in a configuration system. A longitudinal case study was conducted to compare cost and time-estimation accuracy before and after implementation. We conclude that the proposed method for grouping costs, combined with a PCS, can be used in project-based construction industries to make more accurate estimates of project costs. Reasons for improved accuracy are, according to company experts, the increased documentation and visibility of cost-estimates, dynamic allocation of variable costs, version control of cost-agreements and the ability to handle an increased level of cost details.

Indicators for environmental sustainability
Decision making on sustainable consumption and production requires scientifically based information on sustainability. Different environmental sustainability targets exist for specific decision problems. To observe how well these targets are met, relevant environmental indicators are needed. In this study, we reviewed indicators applied in life cycle assessment (LCA), planetary boundary framework (PB), and Sustainable Development Goals (SDGs) developed under United Nation. The aim is to 1) identify their applications and relevant decision context; 2) Review their indicators and categorize them into Drivers-Pressures-States-Impacts-Responses scheme for comparison and; 3) provide suggestions for indicator system choice and important aspects to consider when choosing.

Industrial excess heat for district heating in Denmark

Excess heat is available from various sources and its utilisation could reduce the primary energy use. The accessibility of this heat is however dependent amongst others on the source and sink temperature, amount and potential users in its vicinity. In this work a new method is developed which analyses excess heat sources from the industrial sector and how they could be used for district heating. This method first allocates excess heat to single production units by introducing and validating a new approach. Spatial analysis of the heat sources and consumers are then performed to evaluate the potential for using them for district heating. In this way the theoretical potential of using the excess heat for covering the heating demand of buildings is determined. Through the use of industry specific temperature profiles the heat usable directly or via heat pumps is further found. A sensitivity analysis investigates the impact of future energy efficiency measures in the industry, buildings and the district heating grid on the national potential. The results show that for the case study of Denmark, 1.36 TWh of district heat could be provided annually with industrial excess heat from thermal processes which equals 5.1% of the current demand. More than half of this heat was found to be usable directly, without the need for a heat pump.

Information-triggered Co-evolution: A Combined Process Perspective

Core elements of design work include the development of problem/solution understanding, as well as information and knowledge sharing activities. However, their interrelationships have been little explored. As such, this work aims to take the first steps towards a more integrated evaluation and description of the interaction between understanding and activity, based around co-evolutionary transition events; and start to answer the question: How can the link between co-evolution and activity be systematically characterized as a foundation for a more fundamental description of design activity? A protocol analysis is used to provide the basis for characterization of different types of coevolutionary transition event. A number of distinct event types are described and significant differences in information use and team engagement are identified across transition events. Bringing these findings together, we propose a unitary model of the interaction between activity and understanding around co-evolutionary transition events. This has a number of implications for future theory building and testing in both design activity and wider design research.

Innovation Dialectics: An Extended Process Perspective on Innovation in Services

Services are characterized by the involvement of customers and other interest groups in the innovation process. The aim of this study is to understand how and why, in the service context, tensions and potential conflicts between heterogeneous interest groups unfold during processes of innovation. The empirical field in which the investigation was set is facility services, a type of business-to-business support services. The findings were extracted from a longitudinal, in-depth case
study of a Danish, multi-national organisation over 13 years, complemented with an explorative study in the Danish facility service context. The findings suggest that tensions and conflicts between heterogeneous interest groups are an intrinsic element of innovation processes in services, and that emphasising them might actually support a clearer understanding of processes of innovation in services. The outcome of the analysis is a process model, which proposes innovation dialectics as one of the driving mechanisms of innovation in services.

Integer programming techniques for educational timetabling

Educational timetabling problems require the assignment of times and resources to events, while sets of required and desirable constraints must be considered. The XHSTT format was adopted in this work because it models the main features of educational timetabling and it is the most used format in recent studies in the field. This work presents new cuts and reformulations for the existing integer programming model for XHSTT. The proposed cuts improved hugely the linear relaxation of the formulation, leading to an average gap reduction of 32%. Applied to XHSTT-2014 instance set, the alternative formulation provided four new best known lower bounds and, used in a matheuristic framework, improved eleven best known solutions. The computational experiments also show that the resulting integer programming models from the proposed formulation are more effectively solved for most of the instances.

Integrated climate change risk assessment: A practical application for urban flooding during extreme precipitation

Risk assessments of flooding in urban areas during extreme precipitation for use in, for example, decision-making regarding climate adaptation, are surrounded by great uncertainties stemming from climate model projections, methods of downscaling and the assumptions of socioeconomic impact models. The multidisciplinary character of such risk assessments also requires that research groups and experts from different scientific disciplines combine knowledge and share model outputs. This paper describes an integrated framework and tool, the Danish Integrated Assessment System (DIAS), which has been designed to address the complex linkages between the different kinds of data required in assessing climate adaptation. It emphasizes that the availability of spatially explicit data can reduce the overall uncertainty of the risk assessment and assist in identifying key vulnerable assets. The usefulness of such a framework is demonstrated by means of a risk assessment of flooding from extreme precipitation for the city of Odense, Denmark. A sensitivity analysis shows how the presence of particularly important assets, such as cultural and historical heritage, may be addressed in assessing such risks. The output of the risk assessment for Odense indicates that highly detailed geographical data reduce the overall uncertainty and assist climate adaptation decision-makers in focusing on protecting those assets that are considered to be relevant in the given context. Also, using an integrated framework such as DIAS enables the relative importance of the different factors (i.e. degree of climate change, assets value, discount rate etc.) to be determined, thus influencing the overall output of the assessment.

Integrated Rolling Stock Planning for Suburban Passenger Railways

One of the core issues for operators of passenger railways is providing sufficient number of seats for passengers while keeping operating costs at a minimum. The process a railway operator undertakes in order to achieve this is called rolling stock planning. Rolling stock planning deals with deciding how to utilise the fleet of available train units in space and time. In this thesis, rolling stock planning has been studied, using as case study DSB S-tog, the suburban passenger railway operator of the City of Copenhagen. At DSB S-tog, the rolling stock planning process is subdivided according to time horizon into two subprocesses. Firstly, there is the long-term circulation planning process, in which planning is conducted for anonymous, virtual train units months in advance. Secondly, there is the short-term train unit dispatching process, which covers the execution of the long term circulation plan. In the train unit dispatching process, the anonymous, virtual train units from the circulation planning process will have real, physical train units assigned to them. The train unit dispatching process has a short-term time horizon of days, hours and minutes and makes sure the actual, real-world train services are performed. Disruptions are also handled in this process. In the long term circulation planning phase of rolling stock planning, a large number of railway-specific requirements must be taken into account: The physical railway infrastructure must be adhered to, e.g., platform and depot track capacities, the rules of the train control system and the order in which train units may be parked so as not to obstruct each other’s movements; All trains services of the timetable must have a least one train unit assigned; Only the available rolling stock can be used in the plan; The plan should provide seating capacity according to the passenger demand and provide an even distribution of flexible space for bicycles etc.; Planned shunting operations in the depot should have sucient personnel on duty; Train units must undergo interior and exterior cleaning, surface foil application and winter preparedness treatment at regular time intervals; At regular service distance intervals, train units must undergo scheduled maintenance etc., and consumables must be reﬁlled; Certain train services must have train units with additional train control system equipment installed, special passenger counting equipment installed and/or perform predefined exposure of commercials.

In the short-term train unit dispatching phase of rolling stock planning, additional railwayspecific requirements include: Exterior graffiti removal and unscheduled maintenance on demand and sometimes within a given time frame; Make available train units to meet surveillance video recording requests from the police within a given time frame. Due to the large number of railway-specific requirements and their nature, rolling stock planning is traditionally conducted in a step-by-step manner, in which the individual planning processes are not integrated with each other. Needless to say, this yields rolling stock plans that are either suboptimal or infeasible with regard to the requirements. In this thesis it is shown that it is possible to design and implement a rolling stock planning model integrating into one planning process all the railway-specific requirements of DSB S-tog, all at the same time. This integrated rolling stock planning model is implemented using a greedy heuristic and makes use of the novel (train) unit order conservation principle, implemented as special side constraints to a resource constrained shortest path algorithm. The integrated rolling stock planning model is tested extensively on 15 real-world, manually constructed rolling stock plan data instances. When run on these instances, the greedy heuristic can achieve an average economic gain of approx. 2% with processing times in all cases less than 1 hour 20 minutes. In addition to this, the greedy heuristic can make typically infeasible rolling stock plans feasible within just a few minutes of processing time. Moreover, in this thesis a number of different economic net value upper bound calculation models are designed, implemented and tested. The net value upper bound calculation models implement the railway-specific requirements to a varying degree and consequently expose different properties with regard to tightness of bounds and processing times. The net value upper bound model having the highest degree of requirements integration adheres to 47% of the requirements by count. Using this tightest net value upper bound calculation model, it is shown that the greedy heuristic mentioned before is able to gain approx. 1/3 of the relative gap between the net value of the original, manual plans and the net value upper bound. Moreover, it is shown that in most cases, the net value of the original, manual plans already lie close to the upper bound.

Furthermore, a branch-and-price based matheuristic integrated rolling stock planning model is designed, implemented and tested. It is shown that this type of matheuristic model is able to adhere fully to all railway-specific requirements, and that the vast majority of requirements can be integrated into the optimisation steps of the atheuristic algorithm. The branch-and-price matheuristic model can solve small instances (e.g., in the form of matheuristic iterations) to optimality. Used in conjunction with the greedy heuristic, the two methods combined can achieve an additional small gain in objective value not achievable using each method by itself. With a yearly cost of the rolling stock operation in the hundreds of million DKK, the potential benefit of a real-world application of the models to DSB S-tog is in the order of several million DKK per year. In addition to this, a substantial benefit can be gained by the way the models can automate the current, manual planning procedures. This will enable planners to invest more creativity and meticulousness into the planning process as a result of being liberated from manual planning procedures. For these reasons, DSB S-tog is eager to proceed with the real-world application of the models developed in this thesis.
Integrating experiences from operations into engineering design: modelling knowledge transfer in the offshore oil industry

Summative Statement: Integrating human factors and users' experiences in design projects is a well-known challenge. This study focus on the specific challenges for transferring these experiences and how using a knowledge transfer model can help this integration on the design of high-risk productive work systems, such as offshore oil rigs.

Problem statement: Poorly designed workspaces result in adverse effects on occupational health and safety, as well as reduced efficiency and productivity. In large-scale engineering projects and, in special the offshore oil sector that has to face geographical and workwise distance between operations and engineering design teams, integrating human factors and transferring knowledge are key aspects when designing for better performance systems.

Research Objective: Based on an in-depth empirical investigation in an offshore oil company, this study aims to provide a framework for the knowledge transfer process from operations into engineering design that helps identifying and facing the challenges for such a transfer process.

Methodology: The study was carried out as a case study in an offshore oil company. We used the empirical data collected through interviews and surveys to identify the main challenges for the knowledge transfer process based on a pragmatic 4-step framework. At a later stage, we developed a set of requirements to improve the knowledge transfer from operations into design.

Results: Knowledge transfer implies the knowledge to be 1) captured on the operating units, 2) transformed into an engineering design context, 3) transferred to the appropriate project team members, and finally 4) applied throughout the design process of new installations. It is a fourstep process involving challenges going from not having specific performance indicators encouraging rig workers to focus on capturing knowledge targeted to design to not having this knowledge available to be applied at the right time in the projects, making it at times impossible to implement in terms of design specifications. Challenges also pass through dealing with the large amount of knowledge registered in the systems without standards to categorise and store this knowledge, to being difficult to access and retrieve the knowledge in the systems.

Discussion: Transferring knowledge and experiences from users brings human factors into play and modelling the knowledge transfer process provides a better idea of what is involved. The entire process requires a continuous flow in order to develop a permanent repository that is continuously updated and is used to optimise the design towards better system performance. Overall, the requirements developed based on the identified challenges point to the need to have clear procedures and standards to capture the operational knowledge, as well as an alignment of the key performance indicators related to the knowledge transfer process, since it will allow for better collaboration and communication between the two divisions. Furthermore, clear methods and resources to systematise and transform the knowledge, together with appropriate methods to make it available to the project teams are paramount.

Conclusions: Using a framework helps to identify challenges is of importance for both practitioners and researchers, since it 1) helps developing practical requirements for improving knowledge transfer and 2) supports framing the knowledge transfer process in a systematic way, allowing for comparison within different cases towards generalising the findings.
Integrating Lean and employee involvement in developing the work process and well-being in a hospital setting

Integrating robust timetabling in line plan optimization for railway systems
We propose a heuristic algorithm to build a railway line plan from scratch that minimizes passenger travel time and operator cost and for which a feasible and robust timetable exists. A line planning module and a timetabling module work iteratively and interactively. The line planning module creates an initial line plan. The timetabling module evaluates the line plan and identifies a critical line based on minimum buffer times between train pairs. The line planning module proposes a new line plan in which the time length of the critical line is modified in order to provide more flexibility in the schedule. This flexibility is used during timetabling to improve the robustness of the railway system. The algorithm is validated on the DSB S-tog network of Copenhagen, which is a high frequency railway system, where overtakings are not allowed. This network has a rather simple structure, but is constrained by limited shunt capacity. While the operator and passenger cost remain close to those of the initially and (for these costs) optimally built line plan, the timetable corresponding to the finally developed robust line plan significantly improves the minimum buffer time, and thus the robustness, in eight out of ten studied cases.

Integrating rolling stock scheduling with train unit shunting

In this paper, we consider integrating two important railway optimization problems, in particular the Rolling Stock Scheduling Problem and the Train Unit Shunting Problem. We present two similar branch-and-cut based approaches to solve this integrated problem and, in addition, provide a comparison of different approaches to solve the so-called Track Assignment Problem, a subcomponent of the Train Unit Shunting problem. In this analysis we demonstrate, by way of a counter example, the heuristic nature of a previously argued optimal approach. For the integrated problem we analyze the performance of the proposed approaches on several real-life case studies provided by DSB S-tog, a suburban train operator in the greater Copenhagen area. Computational results confirm the necessity of the integrated approach; high quality solutions to the integrated problem are obtained on instances where a conventional, sequential approach ends in infeasibility. Furthermore, for the considered instances, solutions are typically found within a few minutes, indicating the applicability of the methodology to short-term planning.

Integrating Work Environment Considerations Into Lean and Value Stream Mapping

Public healthcare systems and in particular hospitals in industrialized countries face growing demand in terms of number of patients and new advanced treatments. Funding does not increase proportionately and hospitals are ever searching for methods to increase productivity. Lean management has emerged a dominant approach to increase productivity in healthcare (Edwards et al. 2012, Radnor, Holweg, & Waring, 2012). In Denmark lean management has become widely used with hospitals developing their own lean departments and consultants. Lean management is developed in the car manufacturing industry (Spear & Bowen, 1999; Womack & Jones, 1996) and is based on standardisation, levelling, and optimisation of work flows through value stream mapping (VSM) (Rother & Shook, 2009) and eliminating waste. Lean is essentially a rationalization approach that will reduce waste and increase productivity thereby causing work intensification (Westgaard & Winkel, 2011) with negative impact on work environment. To compensate for the negative effects of lean a work environment complement (ErgoVSM) has been developed in Sweden (Jarebrandt et al. 2010). ErgoVSM integrate work environment considerations into VSM by introducing work environment measurements to be assessed for each identified work activity. The measurements are: 1) Physical: a) work posture, b) weight/force, c) physical load, d) potential, e) porosity and f) variation. And 2) psychosocial dimensions: a) Demands, b) control, c) communication, d) potential, e) mental porosity and f) variation in contents. However, lean management and the VSM analysis focus on waste to identify workflow problems and develop an improved workflow. The lean mindset and waste analysis is taught to work shop participants by a lean coach. The focus and mindset of reducing waste is much different from identifying and discussing work environment problems and there might be a tension between the two perspectives. Subsequently it may not be possible to integrate work environment considerations into lean and VSM. The purpose of this presentation is to examine if it is possible to integrate work environment considerations into lean and VSM. This is done by applying the ErgoVSM method as part of a normal lean intervention. The paper will answer if ErgoVSM can identify physical and psychosocial work environment problems and develop solutions as part of lean and VSM.

Integration of Fiber-Reinforced Polymers in a Life Cycle Assessment of Injection Molding Process Chains with Additive Manufacturing

Additive manufacturing technologies applied to injection molding process chain have acquired an increasingly important role in the context of tool inserts production, especially by vat polymerization. Despite the decreased lifetime during their use in the injection molding process, the inserts come with improvements in terms of production time, costs, exibility, as well as potentially improved environmental performance as compared to conventional materials in a life cycle perspective. This contribution supports the development of additively manufactured injection molding inserts with the use of fiber-reinforced vat polymerization technology. The life cycle assessment of the prototyping process chain with high exibility provides a base for industrial applications in injection molding.

International cooperative initiatives and the United Nations Framework Convention on Climate Change

International cooperative initiatives (ICIs) are multi-country, multi-actor non-state actions that have the potential to reduce emissions of greenhouse gases. The article summarizes the literature on estimates of emission reduction potentials attributed to ICIs. This summary highlights three key issues: there is a plethora of uncoordinated initiatives, often lacking specific, time-bound goals; to a greater or lesser extent most initiatives overlap with the activities conducted under the aegis of the United Nations Framework Convention on Climate Change (UNFCCC); and few initiatives have set up transparent performance monitoring and reporting mechanisms. The article concludes with two considerations. Firstly, it advocates for the United Nations Environment Programme as one entity that could bring much-needed coordination among ICIs, and between ICIs and national government-led efforts to mitigate climate change. Secondly, it echoes calls for the initiatives to both adopt transparent monitoring, reporting and verification mechanisms, and ensure that their activities are cost-effective with regard to climate change mitigation. Finally, the article outlines the key issues that will need to be addressed to achieve these goals.

Key policy insights
• The emission reductions potential of international cooperative initiatives appears to be limited, which would question some of the rational for promoting them.
• The extent to which international cooperative initiatives overlap with emission reduction efforts under the UNFCCC is uncertain, but believed to be quite large.
• The UNFCCC is arguably ill suited to coordinate and strengthen the accountability of international cooperative initiatives.

In times of change: How distance managers can ensure employees' wellbeing and organizational performance

Organizations develop and adapt to societal changes and technological developments, where one consequence is that dispersed workers are more common than never before. It is difficult to ensure employee wellbeing and performance, when separating managers from employees by either time or geography. This paper explores the wellbeing of employees doing distance work, and examines the practices of the distance manager aimed at ensuring employee wellbeing and organizational performance. The pilot study use a case study approach in four organizations with qualitative interviews of distance managers and employees. The study show both positive and negative aspects of distance work. Positively, the employees find distance work to be professionally challenging and they feel they make a difference in their work. On the negative side is the feeling of loneliness and frustrations about lack of communication. The analysis of distance managers' practices showed that they used both activities and capabilities in order to ensure employee wellbeing and organizational performance. The activities included planning, newsletters, and surveys, and the capabilities were to listen, create and show trust, and give authority to the employees. Contrary to previous findings on motivating of knowledge workers, our findings show that motivation, surprisingly, is ensured when focusing on the basic needs such as working conditions and belongingness.

Intraday market asymmetries — A Nordic example

While the majority of electricity in the Nordic and Baltic countries is traded at the day-ahead market, producers and consumers can use the intraday market to adjust their production commitments according to updated forecasts closer to the time of delivery. This reduces the need for balancing, particularly important for VRE producers, but it also means that the price formation at intraday market can change optimal bidding strategy in the day-ahead market. Through econometric modelling of intraday price premiums, this paper investigates intraday price asymmetries, which potentially can lead to strategic bidding. The intraday market is per definition symmetric, as prices for power sales always correspond to prices for power purchases, however, we find that this symmetry is not reflected in the price structure in regards to the total load adjustment needs.

Introduction to LCA Methodology
In order to offer the reader an overview of the LCA methodology in the preparation of the more detailed description of its different phases, a brief introduction is given to the methodological framework according to the ISO 14040 standard and the main elements of each of its phases. Emphasis is on the iterative nature of the LCA process with its many feedback loops between the different phases. It is explained how the integrated use of sensitivity analysis helps identify key assumptions and key data and thus ensure effectiveness by directing the focus of the LCA practitioner to those parts of the study where additional work contributes most to strengthen the results and conclusions of the study.

Investigating the influence of product perception and geometric features
Research in emotional design and Kansei Engineering has shown that aesthetics play a significant role in the appeal of a product. This paper contributes to establishing a methodology to identify the relationships between perceptions, aesthetic features, desire to own and background of consumers. Surveys were conducted with 71 participants to gather their perceptions of 11 vase concepts. Advanced statistical analyses, including mixed models, were applied to allow generalisation of the results beyond the data sample. Significant relations between the desire to own a product and how the product is perceived were found (the desire to own was found to be related to beautiful, expensive, elegant, exciting, feminine, common and dynamic vases), as well as between the perceptions and the parameters describing the form of the vases (a vase was perceived as beautiful if it had many curved lines and was simple and tall). An automated mixed model analysis was conducted and revealed that general rules can be found between aesthetic features, perceptions and ownership, which can apply across gender and culture. The findings include design rules that link aesthetic features with perceptions. These contribute to research as guidelines for design synthesis and can either be implemented via shape grammars or parametric modelling approaches. These rules are also interesting for 3D printing applications, especially important when the consumer is the designer. Some of these design rules are linked to the desire to own a product, they have implications for industry, and they offer guidelines to creating attractive products that people want to own.
Investigating the reasons behind the intention to report cycling crashes to the police and hospitals in Denmark

This study explores the factors underlying the reporting intentions of cycling crashes by looking at barriers to reporting from other contexts and eliciting them via a survey and a structural equation model (SEM). The barriers consist of the attitude that crash reporting is useless, the preference to allocate time to other activities, the concerns about family distress and social image, the distrust in the police, and the medical consultation aversion. The survey elicited the reasons as well as socio-economic characteristics, cycling habits and last crash experience of cyclists, and yielded 1512 complete responses that were used for SEM estimation. The empirical analysis revealed that: (i) distrust in the police and medical consultation aversion are related to the reporting intentions both directly and indirectly through the attitude that crash reporting is useless and the preferences to allocate time to other activities; (ii) medical consultation aversion has a higher weight than the distrust in the police in demotivating cycling crash reporting intentions; (iii) the reasons are all strongly related to cyclists' characteristics and last cycling crash characteristics; and (iv) information provision regarding the societal benefits of crash reporting is important for increasing the reporting rate. Investigating the relationship between sustainability and business model innovation in the context of the European food industry

Organisations, and society at large, are nowadays facing enormous and unprecedented challenges in terms of sustainable development (United Nations General Assembly 2015). Therefore, there is an increasing necessity to prioritize sustainability concerns, and ensure the integration of sustainability into organisations' business models. Such a prioritization and integration can in turn generate new opportunities to innovate and differentiate business models (Bocken et al. 2014), and, consequently, be decisive for organisations that want to sustain their competitiveness in the market (Teece 2010; Gambardella & McGahan 2010). Thus, on one hand, business model innovation can help to achieve significant improvements in terms of sustainability (Breuer and Lüdeke-Freund, 2017; Carayannis et al., 2015; Pedersen et al., 2016; Rauter et al., 2017; Schaltegger et al., 2012). On the other, sustainability has the potential to inspire and drive business model innovation (Bocken et al., 2014; Joyce and Paquin, 2016). As effectively explained by Ernesto Ciorra, Head of Innovation and Sustainability at Enel, “we are not sustainable unless we innovate, and in order to innovate, we have to be sustainable” (Global Reporting Initiative 2016). The current study aims to investigate the relationship between sustainability and business model innovation within the European food industry. Empirically, the analysis is based on survey data from 469 companies of seven European countries, namely Denmark, France, Germany, Italy, Netherlands, Spain, and United Kingdom. The overall results show that sustainability is slightly positively related to business model innovation. This seems to be particularly true for German companies, which show a high positive relationship. The result does not hold true for Danish companies, which show a slightly negative relationship. This study has implications for practitioners and scholars who work in the field of sustainability and business model innovation, especially in the context of the European food industry.

Is Earth recognized as a finite system in corporate responsibility reporting?

Companies are increasingly encouraged to frame their sustainability activities and communication around ecological limits, as captured by concepts such as planetary boundaries, climate tipping points or regenerative capacity. Ecological limits may serve as scientific basis for defining environmental sustainability targets at the company level and, moreover, inspire companies to align their product portfolios with emerging societal needs related to sustainable transformations. Although corporate environmental reporting is widely researched, little attention has, hitherto, been given to company use of the ecological limits concepts in stakeholder communication. This study presents a comprehensive review of references made to ecological limits in corporate responsibility (CR) reports in 2000-2014. An exhaustive list of terms related to ecological limits was developed and used to search the CorporateRegister database, which contained approximately 40,000 CR reports from this time period. For every identified reference, we analyzed the context in which the ecological limit term was
used in the CR report. We found a 10-fold increase in the number of references made to ecological limits in CR reports during the period 2000-2014. The number of CR reports published in this time period has also increased at a similar rate. Hence, the proportion of companies referring to ecological limits in their CR reports has over the years remained stable; roughly 5%. The most commonly invoked ecological limits were related to climate change and references to “2°C” were by far the most frequent. The vast majority of companies referring to ecological limits did so without specific references to ongoing or planned changes in their activities as a consequence of recognizing these limits. Only a small percentage, predominately high-tech companies (31 in total), explicitly used ecological limits to define targets for resource consumption, emissions reductions and/or as a stated reason for adjusting their product portfolio. In defining targets for resource consumption or emissions, only a few CR reports dealt explicitly with the issue of allocating resource and emission rights within ecological limits amongst companies and other actors. A longitudinal study of three companies showed that these did not directly report progress towards planned changes based on ecological limits and offered explanations as to why some companies abandoned planned changes altogether. Our findings provide novel insights into the current use of the ecological limits concept by companies and may be useful for actors trying to motivate companies to align their activities with the finite nature of Earth’s natural systems.

Knowledge sharing via social media in software development: a systematic literature review

Effective knowledge exchange among software developers is crucial for the competitive performance of their organizations. Today, the constant pressure on businesses to continually innovate and the increasing capability of information technologies to facilitate broader and more distributed communication are driving organizations to leverage social media tools to improve performance. These tools, which have changed the way we share knowledge, enable people to connect, communicate, and collaborate. Research on knowledge sharing via social media is still in its early phases, with a comprehensive overview of the literature yet to be completed. Thus, using a systematic literature review approach, this study aims to map the current literature on the topic in relation to software development. Furthermore, this study highlights the findings of former research and identifies gaps in the literature. The study offers several insights for researchers and practitioners and proposes a future research agenda to strengthen knowledge in the field.

Knowledge transfer from building operation to construction.

Purpose: To investigate how knowledge that derives from operation and maintenance of buildings can be stored and transferred in order to be reused in a future building project? Design/methodology/approach: The paper is theoretically based on knowledge management with a particular focus on interdepartmental knowledge transfer between departments responsible for operation and management and departments responsible for building projects in organisations with large and fast changing building portfolios. The paper includes a case study of the FM organisation of the Technical University of Denmark with data collection mainly by interviews with managers and staff in the relevant departments in this organisation. Findings: The case organisation seems to be aware of the importance of sharing and transferring their organisational knowledge. Over the last five years, the organisation has developed different tools and adopted several processes, aiming to the integration of the knowledge they possess from many years of operation and maintenance of the existing buildings. However, there are many situations, where the tools and processes do not work efficiently, and therefore the knowledge transfer is not sufficiently effective. It is apparent that the best results can be achieved only if the different actors involved in a construction project collaborate aiming towards the same objectives. Originality/value: The paper presents and evaluates a case of interdepartmental knowledge transfer in an organisation, which has a strong focus on improving the interconnections between building operation and planning new building projects.
LCA and Sustainability
LCA is often presented as a sustainability assessment tool. This chapter analyses the relationship between LCA and sustainability. This is done by first outlining the history of the sustainability concept, which gained momentum with the Brundtland Commission’s report ‘Our Common Future report’ in 1987, and presenting the most common interpretations of the concept, which generally comprise four dimensions: (1) measures of welfare, (2) inter-generational equity, (3) intra-generational equity and (4) interspecies equity. The relevance of environmental protection for dimensions 2 and 4 is then demonstrated, and the strategy of LCA to achieving environmental protection, namely to guide the reduction of environmental impacts per delivery of a function, is explained. The attempt to broaden the scope of LCA, beyond environmental protection, by so-called life cycle sustainability assessment (LCSA) is outlined. Finally, the limitations of LCA in guiding a sustainable development are discussed.

LCA Applications
The chapter gives examples of applications of LCA by the central societal actors in government, industry and citizens, and discusses major motivations and challenges for the use of LCA to support science-based decision-making from their respective perspectives. We highlight applications of LCA in policy formulation, implementation and evaluation, present different purposes of LCA application in industry at both product and corporate levels, and discuss challenges for LCA applications in small- and medium-sized enterprises. Our synthesis demonstrates the importance of LCA as a tool to quantify environmental impacts of products and systems and support decisions around production and consumption and highlights factors that prevent its even more widespread application.

LCA Cookbook

The LCA cookbook presents the provisions and actions from the ILCD Handbook that are central in the performance of an LCA. The selection is intended to cover all those activities that an LCA practitioner needs to undertake in a typical process-LCA, and the presentation follows the normal progression of the LCA work according to the ISO framework. For explanation of the reasoning behind the actions, the reader is referred to the presentation of the methodological elements in Part 2 of the book.

LCA History
The idea of LCA was conceived in the 1960s when environmental degradation and in particular the limited access to resources started becoming a concern. This chapter gives a brief summary of the history of LCA since then with a focus on the fields of methodological development, application, international harmonisation and standardisation, and dissemination. LCA had its early roots in packaging studies and focused mainly on energy use and a few emissions, spurring a largely un-coordinated method development in the US and Northern Europe. Studies were primarily done for companies, who used them internally and made little communication to stakeholders. After a silent period in the 1970s, the 1980s and 1990s saw an increase in methodological development and international collaboration and coordination in the scientific community and method development increasingly took place in universities. With the consolidation of the methodological basis, application of LCA widened to encompass a rapidly increasing range of products and systems with studies commissioned or performed by both industry and governments, and results were increasingly communicated through academic papers and industry and government reports. To this day, methodological development has continued, and increasing attention has been given to international scientific consensus building on central parts of the LCA methodology, and standardisation of LCA and related approaches.

LCA of Biofuels and Biomaterials
Biofuels and biomaterials can today substitute many commodities produced from fossil resources, and the bio-based production is increasing worldwide. As fossil resources are limited, and the use of such resources is a major contributor to global warming and other environmental impacts, the potential of bio-products as substitutes for fossil-based products is receiving much attention. According to many LCA studies, bio-products are environmentally superior to fossil products in some life cycle impact categories, while the picture is often opposite in others. Bio-products is a highly diverse group of products and the environmental profile of bio-products relative to their fossil counterparts is case specific and to a high degree depending on the feedstock used. This illustrates the importance of conducting case specific LCAs for determining the environmental profile of bio-products relative to fossil ones, and emphasises the importance of including all relevant impact categories, in order to avoid problem shifting.

LCA of Buildings and the Built Environment
How we design human settlements has a profound influence on society's environmental pressures. This chapter explores the current state of LCA applied to two scales of human settlements; individual buildings and the built environment, where the built environment is understood as a collection of autonomous buildings along with the infrastructure and human activity between those buildings. The application of LCA to buildings has seen growing interest in recent years, partly as a result of the increased application of environmental certification to buildings. General findings are that the use stage of the building tends to dominate environmental impacts, though as buildings become increasingly energy efficient, life cycle impacts shift towards other stages. LCA of built environments has been a useful supplement to mass-based urban environmental assessments, highlighting the importance of embodied environmental impacts in imported goods and showing interesting trade-offs between dense urban living and the greater purchasing power of wealthy urbanites. LCAs of human settlements also face difficult challenges; the long use stage (often decades) introduces high uncertainty regarding the end-of-life stage; evolving electrical mixes throughout the use stage; gaps in consumption data at the city level. This chapter endeavours to elucidate the strengths, research needs and methodological shortcomings of LCA as applied to buildings and the built environment, showing that they can act as complimentary tools to help society's shift towards a sustainable future.

LCA of Chemicals and Chemical Products
This chapter focuses on the application of Life Cycle Assessment (LCA) to evaluate the environmental performance of chemicals as well as of products and processes where chemicals play a key role. The life cycle stages of chemical products, such as pharmaceuticals drugs or plant protection products, are discussed and differentiated into extraction of abiotic and biotic raw materials, chemical synthesis and processing, material processing, product manufacturing, professional or consumer product use, and finally end-of-life. LCA is discussed in relation to other chemicals management frameworks and concepts including risk assessment, green and sustainable chemistry, and chemical alternatives assessment. A large number of LCA studies focus on contrasting different feedstocks or chemical synthesis processes, thereby often conducting a cradle to (factory) gate assessment. While typically a large share of potential environmental impacts occurs during the early product life cycle stages, potential impacts related to chemicals that are found as ingredients or residues directly in products can be dominated by the product use stage. Finally, methodological challenges in LCA studies in relation to chemicals are discussed including the choice of functional unit, defining the system boundaries, quantifying emissions for many thousands of marketed chemicals, characterising emissions in terms of toxicity and other impacts, and finally interpreting LCA results. The chapter is relevant for LCA students and practitioners who wish to gain basic understanding of LCA studies of products or processes with chemicals as a key aspect.

LCA of Energy Systems
Energy systems are essential in the support of modern societies' activities, and can span a wide spectrum of electricity and heat generation systems and cooling systems. Along with their central role and large diversity, these systems have been demonstrated to cause serious impacts on human health, ecosystems and natural resources. Over the past two decades, energy systems have thus been the focus of more than 1000 LCA studies, with the aim to identify and reduce these impacts. This chapter addresses LCA applications to energy systems for generation of electricity and heat. The chapter gives insight into the LCA practice related to such systems, offering a critical review of (i) central methodological aspects, including the definition of the goals and scopes of the studies, their coverage of the system life cycle and the environmental impacts, and (ii) key findings of the studies, particularly aimed at identifying environmental hotspots and impact patterns across different energy sources. Based on this literature review recommendations and guidelines are issued to LCA practitioners on key methodological aspects that are important for a proper conduct of LCA studies of energy systems and thus ensuring the reliability of the LCA results provided to decision- and policy-makers.

LCA of Food and Agriculture
This chapter deals with the application of Life Cycle Assessment to evaluate the environmental sustainability of agriculture and food processing. The life cycle of a food product is split into six stages: production and transportation of inputs to the farm, cultivation, processing, distribution, consumption and waste management. A large number of LCA studies focus on the two first stages in cradle-to-farm gate studies, as they are the stages where most impacts typically occur, due to animal husbandry and manure handling, production and use of fertilisers and the consumption of fuel to operate farm machinery. In the processing step, the raw agricultural product leaving the farm gate is converted to a food item that can be consumed by the user. Distribution includes transportation of the food product before and after processing. In the consumption stage, environmental impacts arise due to storage, preparation and waste of the food. In the waste management stage, food waste can be handled using a number of technologies, such as landfilling, incineration, composting or digestion. A number of case studies are looked at here where the life cycles of typical food products (meat, cheese, bread, tomatoes, etc.), and an entire diet are discussed. Other case studies deal with what LCA can conclude on the differences between conventional and organic farming, and the perceived advantages of local food items. Finally, methodological issues in agricultural LCA are discussed: the choice of functional unit, setting the boundary between technosphere and ecosphere, modelling flows of nutrients and pesticides, and the generally limited number of impact categories included in LCA studies.

LCA of Nanomaterials
Application of nanomaterials in products has led to an increase in number of nanoproducts introduced to the consumer market. However, along with new and improved products, there is a concern about the potential life cycle environmental impacts. Life cycle assessment is able to include a wide range of environmental impacts but, due to data limitations, it is commonly applied with focus on the cradle-to-gate part of the nanoproducts life cycle, neglecting use and disposal of the products. These studies conclude that nanomaterials are more energy demanding and have an inferior environmental profile than conventionally used materials, but functional units of these comparisons need to consider the use stage benefits attained through nanomaterials. A particular assessment challenge is the lack of understanding of the toxicological mechanisms related to potential release, fate and effects of nanomaterials when penetrating into living organisms. This is especially relevant for the freshwater compartment, as it is a common recipient.
LCA of Soil and Groundwater Remediation

Today, there is increasing interest in applying LCA to support decision-makers in contaminated site management. In this chapter, we introduce remediation technologies and associated environmental impacts, present an overview of literature findings on LCA applied to remediation technologies and present methodological issues to consider when conducting LCAs within the area. Within the field of contaminated site remediation, a terminology distinguishing three types of environmental impacts: primary, secondary and tertiary, is often applied. Primary impacts are the site-related impacts due to the contamination in the ground, secondary impacts are the impacts related to clean-up of the site, and tertiary impacts are the impacts associated with the future use of the site. The major methodological issues to consider when conducting LCA are: (i) defining a functional unit that considers time frame and efficiency of remediation, which are important for assessment or primary impacts; (ii) robust assessment of primary impacts using site-specific fate and exposure models; (iii) weighting of primary and secondary (or tertiary) impacts to evaluate trade-offs between life cycle impacts from remediation and reduced pressure locally; and (iv) comparison with a no action scenario to determine whether there is a net environmental benefit from remediation. Overall, LCA is an important tool for the assessment of the secondary environmental impacts of remediation, and occasionally it has also been used to assess primary and tertiary impacts. In order to obtain robust decisions for the management of contaminated sites, the combination of LCA with other tools is necessary, including multi-criteria decision analysis tools, site-specific fate and exposure models and consideration of stakeholders’ views.

LCA of Solid Waste Management Systems

The chapter explores the application of LCA to solid waste management systems through the review of published studies on the subject. The environmental implications of choices involved in the modelling setup of waste management systems are increasingly in the spotlight, due to public health concerns and new legislation addressing the impacts from managing our waste. The application of LCA to solid waste management systems, sometimes called “waste LCA”, is distinctive in that system boundaries are rigorously defined to exclude all life cycle stages except from the end-of-life. Moreover, specific methodological challenges arise when investigating waste systems, such as the allocation of impacts and the consideration of long-term emissions. The complexity of waste LCAs is mainly derived from the variability of the object under study (waste) which is made of different materials that may require different treatments. This chapter attempts to address these challenges by identifying common misconceptions and by providing methodological guidance for alleviating the associated uncertainty. Readers are also provided with the list of studies reviewed and key sources for reference to implement LCA on solid waste systems.
LCIA framework and cross-cutting issues guidance within the UNEP-SETAC Life Cycle Initiative

Increasing needs for decision support and advances in scientific knowledge within life cycle assessment (LCA) led to substantial efforts to provide global guidance on environmental life cycle impact assessment (LCIA) indicators under the auspices of the UNEP-SETAC Life Cycle Initiative. As part of these efforts, a dedicated task force focused on addressing several LCIA cross-cutting issues as aspects spanning several impact categories, including spatiotemporal aspects, reference states, normalization and weighting, and uncertainty assessment. Here, findings of the cross-cutting issues task force are presented along with an update of the existing UNEP-SETAC LCIA emission-to-damage framework. Specific recommendations are provided with respect to metrics for human health (Disability Adjusted Life Years, DALY) and ecosystem quality (Potentially Disappeared Fraction of species, PDF). Additionally, we stress the importance of transparent reporting of characterization models, reference states, and assumptions, in order to facilitate cross-comparison between chosen methods and indicators. We recommend developing spatially regionalized characterization models, whenever the nature of impacts shows spatial variability and related spatial data are available. Standard formats should be used for reporting spatially differentiated models, and choices regarding spatiotemporal scales should be clearly communicated. For normalization, we recommend using external normalization references. Over the next two years, the task force will continue its effort with a focus on providing guidance for LCA practitioners on how to use the UNEP-SETAC LCIA framework as well as for method developers on how to consistently extend and further improve this framework.

Learning from participatory design projects across industries

Summative Statement: A preliminary framework for participatory design projects (PDP) was developed based on a retrospective analysis of five PDPs across different industries. The framework may serve as a guidance for planning and conducting PDPs.

Problem statement: A growing number of experiences with participatory design or participatory ergonomics projects have been gained within the field of macro-ergonomics. It is suggested that the Participatory Ergonomics Framework (PEF) validated by Haines et al. (2002) needs to be updated based on these experiences and hence more focuss on design activities.

Research Objective / Question: The objective of this study was to update and design-orient the PEF based on experiences with PDPs within the last ten years.
Methodology: Five participatory design projects across different industries were systematically analyzed and compared in order to develop a framework pointing to supportive theory and practical guidance for ergonomics practitioners. The five PDPs were based in the following industries: construction, public service, food processing, and two healthcare projects. The starting point for the analysis was the notion of work systems meeting each other in the intervention into design projects by ergonomists/researchers.

Results: The nine dimensions and categories in the framework by Haines et al. (2002) are still relevant. However, they are not entirely oriented towards design projects and the framework do not include the dynamics between the ergonomist/researcher and the design activities going on in a company. It is suggested to add the following dimensions to the PEF: Involved work systems, type of interaction between the ergonomist work system and the company design work systems, transfer and integration of results from PDPs into the overall design project in the company.

Discussion: The proposed update of the PEF introduces a dynamic understanding of PDPs by the notion that PDP’s may be seen as interactions between different work systems, including those of the ergonomist/researcher, company designers, consultants, and technology suppliers. By an initial mapping the relevant work systems, the intervention by ergonomists may be better planned and better ensure a real impact on the overall design project. This is of importance because many PDPs have an intermittent and temporary character. The notion of interaction between different work systems also allows for theories on how ergonomists/researchers can impact design projects by facilitating participatory schemes.

Conclusions: This study suggested an updating of the PEF in order to include the dynamics between an ergonomist work systems with its own goals and rationale and a number of company work systems involved in design projects and having other goals and rationales. The updated framework are aimed at guidance in planning and conduction PDPs.

Learning Supervised Topic Models for Classification and Regression from Crowds

The growing need to analyze large collections of documents has led to great developments in topic modeling. Since documents are frequently associated with other related variables, such as labels or ratings, much interest has been placed on supervised topic models. However, the nature of most annotation tasks, prone to ambiguity and noise, often with high volumes of documents, deem learning under a single-annotator assumption unrealistic or unpractical for most real-world applications. In this article, we propose two supervised topic models, one for classification and another for regression problems, which account for the heterogeneity and biases among different annotators that are encountered in practice when learning from crowds. We develop an efficient stochastic variational inference algorithm that is able to scale to very large datasets, and we empirically demonstrate the advantages of the proposed model over state-of-the-art approaches.
Life Cycle Assessment of Fiber-Reinforced Additive Manufacturing for Injection Molding Insert Production

Additively manufactured (AM) injection molding (IM) inserts have proved to be capable to substitute conventionally manufactured metal inserts with polymer-based insert enforced with short, virgin, unseized carbon fibers (CFs). It has been shown that the implementation of AM technology resulted in significant improvements when investigating costs and cycle time for smaller part series. However, being a novel technology, AM inserts yield undesired characteristics, e.g. in terms of potential environmental impact because of the lower lifetime compared to metal inserts. Based on physical performance tests, this contribution provides a comparison of environmental performance of conventionally vs. additively manufactured inserts in a full life cycle perspective indicated in Figure 1, including materials, production, use and end-of-
Life cycle based dynamic assessment coupled with multiple criteria decision analysis: A case study of determining an optimal building insulation level

This work looks at coupling Life cycle assessment (LCA) with a dynamic inventory and multiple criteria decision analysis (MCDA) to improve the validity and reliability of single score results for complex systems. This is done using the case study of a representative Danish single family home over the service life of the building. This case study uses both the established and the coupled MCDA assessment methods to quantify and assess the balance of impacts between the production of mineral wool insulation versus the production of space heat. The use of TOPSIS method for calculating single scores is proposed as an alternative to the ReCiPe single score impact assessment method. Based on the single score impact values obtained from both of these methods, various insulation levels are ranked to determine an ideal insulation level and gauge the effectiveness of environmental impact reduction measures in current Danish building regulations. Using a comparison of the results from the two methods, a preferred choice of impact assessment method is determined. The findings show that if the midpoint impacts for a particular scenario are strongly correlated with a climate change impact indicator, it does not matter which impact assessment is applied. However, for the scenarios where other impact categories vary inversely or independently from the climate change impact indicator, such as with renewable energy production, there is need for a more unconventional method, such as the TOPSIS method, for calculating single score impacts.
There has been significant change in the way buildings are constructed and the way building energy performance is evaluated. Focus on solely the use phase of a building is beginning to be replaced by a life-cycle based performance assessment. This study assesses the environmental impact trade-offs between the heat produced to meet a building’s space heating load and insulation produced to reduce its space heating load throughout the whole life-cycle of a building. To obtain a more realistic valuation of this tradeoff, a dynamic heat production model, which accounts for political projections regarding change in Danish energy supply was used in the analysis. This novel approach of generating inventory for Life Cycle Assessment (LCA) helped to refine an understanding of optimal insulation levels. The findings of this study discourage the over-insulation of houses connected to the district heating grid, which is potentially promoted at present in Danish regulation. It is further concluded that improvement of the mineral wool insulation production process could allow for greater levels of environmentally beneficial insulation and would also help in reducing the overall environmental burden from insulating buildings.

**General information**
Life Cycle Interpretation

The interpretation is the final phase of an LCA where the results of the other phases are considered together and analysed in the light of the uncertainties of the applied data and the assumptions that have been made and documented throughout the study. This chapter teaches how to perform an interpretation. The process of interpretation starts with identification of potentially significant issues in the previous stages of goal and scope definition, inventory analysis and impact assessment, and examples of potential significant issues are given for each phase. The significance is then determined by checking completeness, sensitivity and consistency for each of these identified issues. The outcome is used to inform previous phases on the needs for strengthening the data basis of the study, and where this is not possible to reconsider the goal and scope definition of the study. Finally, guidance is given on how to draw conclusions based on the previous steps of the interpretation, qualify the conclusions in terms of their robustness, and develop recommendations based on the results of the study.

Life Cycle Inventory Analysis
The inventory analysis is the third and often most time-consuming part of an LCA. The analysis is guided by the goal and scope definition, and its core activity is the collection and compilation of data on elementary flows from all processes in the studied product system(s) drawing on a combination of different sources. The output is a compiled inventory of elementary flows that is used as basis of the subsequent life cycle impact assessment phase. This chapter teaches how to carry out this task through six steps: (1) identifying processes for the LCI model of the product system; (2) planning and collecting data; (3) constructing and quality checking unit processes; (4) constructing LCI model and calculating LCI results; (5) preparing the basis for uncertainty management and sensitivity analysis; and (6) reporting.

Life Cycle Management
This chapter gives an overview of Life Cycle Management (LCM)—a discipline that deals with the managerial tasks related to practicing sustainable development in an organisation. Just as Life Cycle Assessment, LCM advocates the life cycle perspective, and it applies this perspective in decision-making processes. The chapter shows that LCA can play a key role in LCM since LCA provides quantitative performance measurements. It also explains, which stakeholders need to be considered, how LCA and LCM relate, how LCA can be used to develop Key Performance Indicators, and addresses how LCM can be integrated into an organisation.
Limitations of experiments performed in artificially made OECD standard soils for predicting cadmium, lead and zinc toxicity towards organisms living in natural soils

Development of comparative toxicity potentials of cationic metals in soils for applications in hazard ranking and toxic impact assessment is currently jeopardized by the availability of experimental effect data. To compensate for this deficiency, data retrieved from experiments carried out in standardized artificial soils, like OECD soils, could potentially be tapped as a source of effect data. It is, however, unknown whether such data are applicable to natural soils where the variability in pore water concentrations of dissolved base cations is large, and where mass transfer limitations of metal uptake can occur. Here, free ion activity models (FIAM) and empirical regression models (ERM, with pH as a predictor) were derived from total metal EC50 values (concentration with effects in 50% of individuals) using speciation for experiments performed in artificial OECD soils measuring ecotoxicological endpoints for terrestrial earthworms, potworms, and springtails. The models were validated by predicting total metal based EC50 values using backward speciation employing an independent set of natural soils with missing information about ionic composition of pore water, as retrieved from a literature review. ERMs performed better than FIAMs. Pearson's r for log10-transformed total metal based EC50s values (ERM) ranged from 0.25 to 0.74, suggesting a general correlation between predicted and measured values. Yet, root-mean-square-error (RMSE) ranged from 0.16 to 0.87 and was either smaller or comparable with the variability of measured EC50 values, suggesting modest performance. This modest performance was mainly due to the omission of pore water concentrations of base cations during model development and their validation, as verified by comparisons with predictions of published terrestrial biotic ligand models. Thus, the usefulness of data from artificial OECD soils for global-scale assessment of terrestrial ecotoxic impacts of Cd, Pb and Zn in soils is limited due to relatively small variability of pore water concentrations of dissolved base cations in OECD soils, preventing their inclusion in development of predictive models. Our findings stress the importance of considering differences in ionic composition of soil pore water when characterizing terrestrial ecotoxicity of cationic metals in natural soils.
Environmental innovation research has not yet clarified how different forms of inbound innovation might exert effects. The current article proposes four driver-based EI types according to two main dimensions: compliance versus voluntary and own value capture versus customer value capture. With a problem-solving perspective, we develop links from different forms of inbound innovation to various types of EI and test the related hypotheses with two waves of the French Community Innovation Survey. On a short-term basis, R&D cooperation and technology acquisition correlate positively with all four types of EI, but over time, persistent R&D cooperation and technology acquisition are associated with EI only at the production stage, according to voluntary/strategic or compliance drivers. Inbound innovation enables quick responses to market demands for EI in the final use stage.
Logic without unique readability - a study of semantic and syntactic ambiguity

One of the main reasons for introducing a formal language is to remove ambiguity, the possibility of assigning several meanings to a linguistic expression. Typically, this is achieved through ensuring unique readability of formulas by using brackets (or another convention, such as Polish notation). Unique readability implies meaning uniqueness, exactly one valuation of a sentence given an interpretation of basic formulas and recursive truth conditions. Obviously, in natural language this one-to-one correspondence between syntax and semantics is absent, the unique readability assumption does not hold true universally. Whereas e.g. scope ambiguities in natural languages have been studied extensively, ambiguous formal languages have not been the focus of in depth research. Here, we lift the assumption of unique readability by omitting the brackets from propositional logic, making it possible to formally distinguish between syntactic and semantic ambiguity. A valuation then amounts to a semantic disambiguation, and rather than a unique valuation (truth value), there is a set of valuations corresponding to ways a formula could have been constructed. We show what happens to familiar concepts of logic such as definability, satisfiability and validity. Here follows two simple examples illustrating the relation between syntactic and semantic ambiguity. In some cases unique readability can be regained through careful construction of formulas. E.g., although an attempt to define \( p \rightarrow q \) as \( \neg p \lor q \) would be syntactically and semantically ambiguous, one may define it as \( q \lor \neg p \), which can be read only one way (but obviously this construction is not stable under substitution). Syntactic ambiguity does not imply semantic ambiguity, although it is typically the case. For instance, although the formula \( p \land \neg p \land p \) can be read in three ways, it has only one possible meaning (a contradiction).

Low Cost and Flexible UAV Deployment of Sensors

This paper presents a platform for airborne sensor applications using low-cost, open-source components carried by an easy-to-fly unmanned aircraft vehicle (UAV). The system, available in open-source, is designed for researchers, students and makers for a broad range of exploration and data-collection needs. The main contribution is the extensible architecture for modularized airborne sensor deployment and real-time data visualisation. Our open-source Android application provides data collection, flight path definition and map tools. Total cost of the system is below 800 dollars. The flexibility of the system is illustrated by mapping the location of Bluetooth beacons (iBeacons) on a ground field and by measuring water temperature in a lake.
Main Characteristics of LCA

Life cycle assessment (LCA) has a number of defining characteristics that enables it to address questions that no other assessment tools can address. This chapter begins by demonstrating how the use of LCA in the late 2000s led to a drastic shift in the dominant perception that biofuels were "green", "sustainable" or "carbon neutral", which led to a change in biofuel policies. This is followed by a grouping of the LCA characteristics into four headlines and an explanation of these: (1) takes a life cycle perspective, (2) covers a broad range of environmental issues, (3) is quantitative, (4) is based on science. From the insights of the LCA characteristics we then consider the strengths and limitations of LCA and end the
chapter by listing 10 questions that LCA can answer and 3 that it cannot.

Make your own product in the Customerpedia
In a configuration system, we use the computers to store, examine, retrieve, and manipulate data related to products, demands and processes. The main consequences are fewer expenses for the customers and more revenue for producers.

Managing innovation processes through value co-creation: a process case from business-to-business service practise
Value co-creation is a specific type of collaboration that is considered to be an innovative and interactive process between end users and organisations; it aims to increase the value of a product or service. This study investigates how a network of stakeholders collaborating to manage innovation openly co-creates value over time; it contributes to the existing literature on value co-creation by taking the perspective of the network as a whole. The study follows a case in which value co-creation unfolds over time across a network of stakeholders within the business-to-business facility service context. The in-depth longitudinal investigation of a network composed of a corporate customer and its external facility service providers revealed that a network of stakeholders co-creates value over time by 1) offering an adaptable structure for the network to organise innovation activities and establish support routines, 2) facilitating interactions to support stakeholder relation development and 3) allowing participants to achieve self-empowerment. Therefore, stakeholder value co-creation entails the combination of single value co-creation activities and overarching network progressions that allow for learning and inter-organisational trust among stakeholders.
Market Prices in a Power Market with more than 50% Wind Power

Denmark has the highest proportion of wind power in the world. Wind power provided a world record of 39.1% of the total annual Danish electricity consumption in 2014 with as much as 51.7% in Western Denmark. Many would argue that the present power markets are not designed for such high shares of wind power production and that it would be hard to get good and stable prices. However, analyses in this chapter show that the Nordic power market works, extreme events have been few, and the current infrastructure and market organization has been able to handle the amount of wind power installed so far. It is found that geographical bidding areas for the wholesale electricity market reflect external transmission constraints caused by wind power. The analyses in this chapter use hourly data from West Denmark—which has the highest share of wind energy in Denmark and which is a separate price area at the Nordic power exchange. Data have been collected from the last ten years and periods with extreme wind conditions are used as case studies to illustrate the robustness of our findings.
Mathematical Programming Approaches for Optimal University Timetabling

Every semester universities are faced with the challenge of creating timetables for the courses. Creating these timetables is an important task to ensure that students can attend the courses they need for their education. Creating timetables that are feasible can be challenging, and when different preferences are taken into account, the problems become even more challenging. Therefore, automating the processes of generating these timetables is a great help for the planners and the universities. Scheduling and timetabling has been studied before in the literature, and two international conferences are dedicated to this research field. This thesis considers a University Timetabling problem, more specifically the Curriculum-based Course Timetabling (CTT) problem. The objective of the CTT problem is to assign a set of lectures to time slots and rooms. The literature has focused mainly on heuristic applications which are also apparent in the different surveys. The drawback of the heuristics is that they are problem specific and do not provide any information on the quality of the solutions they generate. The objective of this thesis is to minimize the gap between the best-known upper bounds and the best-known lower bounds for CTT by using Mixed Integer Programming (MIP) based approaches. We present a total of 15 different MIP based approaches that we have implemented, ranging from Cutting Plane techniques and Lagrangian Relaxation to Benders’ Decomposition and Dantzig-Wolfe Decomposition. Most of these implementations did not provide satisfying results. However, they provide valuable insights into the difficulties of the problem. We discuss all the approaches, the difficulties we have encountered, and suggestions on how to bring research further. Four of the implementations have led to articles submitted to international peer-reviewed journals. The first two articles focus on exact methods and extend each other. The last two focus on generating high-quality lower bounds by applying an extended formulation, which is then decomposed. The articles in this thesis have brought us closer to the goal of closing the gap between the best-known upper and lower bounds for CTT. Though CTT was the problem in focus, the methods implemented here are general enough to be applied for other scheduling problems as well.
The purpose of this study was to investigate the influence of ‘process awareness’ on the creative process of a design team. Process awareness is a cognitive creativity skill which entails actions derived from instances where individuals in the design team express knowledge of underlying cognitive processes and aspects and utilize it to facilitate their own- and their team’s creative process. Transcripts from sessions where the design team...
was working creatively were analyzed both top-down and bottom-up, through quantitative coding, using a coding scheme, and qualitative coding. This was done to ensure capture of all instances of process awareness. Through this iterative process it was revealed that process awareness was predominantly observed in creativity related tasks. Moreover three distinct facets to process awareness emerged; planning, monitoring and reflecting, which were employed respectively before, during and after initiating a process and/or a workshop. We conclude that process awareness is an important creativity skill, being a crucial mechanism to enhance all stages of the creative process. If a designer becomes able to plan, monitor and reflect on his or her own cognitive processes, as well as other team members, he or she will be able to understand what works and what does not for advancing the creative process. In turn, that enables the designer to become more strategic about which actions are appropriate and at what time they are most usefully deployed; making the use of strategies, methods and tools not just an automatic procedure but a highly conscious and purposeful one.

**Metal toxicity characterization factors for marine ecosystems: considering the importance of the estuary for freshwater emissions**

The study develops site-dependent characterization factors (CFs) for marine ecotoxicity of metals emitted to freshwater, taking their passage of the estuary into account. To serve life cycle assessment (LCA) studies where emission location is often unknown, site-generic marine CFs were developed for metal emissions to freshwater and coastal seawater, respectively. The new CFs were applied to calculate endpoint impact scores for the same amount of metal emission to each compartment, to compare the relative ecotoxicity damages in freshwater and marine ecosystems in LCA.

Site-dependent marine CFs for emission to freshwater were calculated for 64 comparatively independent seas (large marine ecosystems, LMEs). The site-dependent CF was calculated as the product of fate factor (FF), bioavailability factor (BF), and effect factor (EF). USEtox modified with site-dependent parameters was extended with an estuary removal process to calculate FF. BF and EF were taken from Dong et al. Environ Sci Technol 50:269–278 (2016). Site-generic marine CFs were derived from site-dependent marine CFs. Different averaging principles were tested, and the approach representing estuary discharge rate was identified as the best one. Endpoint marine and freshwater metals CFs were developed to calculate endpoint ecotoxicity impact scores.

Marine ecotoxicity CFs are 1.5 orders of magnitude lower for emission to freshwater than for emission to seawater for Cr, Cu, and Pb, due to notable removal fractions both in freshwater and estuary. For the other metals, the difference is less than half an order of magnitude, mainly due to removal in freshwater. The site-dependent CFs generally vary within two orders of magnitude around the site-generic CF. Compared to USES-LCA 2.0 CFs (egalitarian perspective), the new site-generic marine CFs for emission to seawater are 1–4 orders of magnitude lower except for Pb. The new site-generic marine CFs for emission to freshwater lie within two orders of magnitude difference from USES-LCA 2.0 CFs. The comparative contribution share analysis shows a poor agreement of metal toxicity ranking between both methods.

Accounting for estuary removal particularly influences marine ecotoxicity CFs for emission to freshwater of metals that have a strong tendency to complex-bind to particles. It indicates the importance of including estuary in the characterization modelling when dealing with those metals. The resulting endpoint ecotoxicity impact scores are 1–3 orders of magnitude lower in seawater than in freshwater for most metals except Pb, illustrating the higher sensitivity of freshwater ecosystems to metal emissions, largely due to the higher species density there.

Model-based corridor performance analysis – An application to a European case

The paper proposes a methodology for freight corridor performance monitoring that is suitable for sustainability assessments. The methodology, initiated by the EU-funded project SuperGreen, involves the periodic monitoring of a standard set of transport chains along the corridor in relation to a number of Key Performance Indicators (KPIs). It consists of decomposing the corridor into transport chains, selecting a sample of typical chains, assessing these chains through a set of KPIs, and then aggregating the chain-level KPIs to corridor-level ones using proper weights. A critical feature of this methodology concerns the selection of the sample chains and the calculation of the corresponding weights. After several rounds of development, the proposed methodology suggests a combined approach involving the use of a transport model for sample construction and weight calculation followed by stakeholder refinement and verification. The sample construction part of the methodology was tested on GreCOR, a green corridor project in the North Sea Region, using the Danish National Traffic Model as the principal source of information for both sample construction and KPI estimation. The results show that, to the extent covered by the GreCOR application, the proposed methodology can effectively assess the performance of a freight transport corridor. Combining the model-based approach for the sample construction and the study-based approach for the estimation of chain-level indicators exploits the strengths of each method and avoids their weaknesses. Possible improvements are also suggested by the paper.
Modeling ecotoxicity impacts in vineyard production: Addressing spatial differentiation for copper fungicides

Application of plant protection products (PPP) is a fundamental practice for viticulture. Life Cycle Assessment (LCA) has proved to be a useful tool to assess the environmental performance of agricultural production, where including toxicity-related impacts for PPP use is still associated with methodological limitations, especially for inorganic (i.e. metal-based) pesticides. Downy mildew is one of the most severe diseases for vineyard production. For disease control, copper-based fungicides are the most effective and used PPP in both conventional and organic viticulture. This study aims to improve the toxicity-related characterization of copper-based fungicides (Cu) for LCA studies. Potential freshwater ecotoxicity impacts of 12 active ingredients used to control downy mildew in European vineyards were quantified and compared. Soil ecotoxicity impacts were calculated for specific soil chemistries and textures. To introduce spatial differentiation for Cu in freshwater and soil ecotoxicity characterization, we used 7 European water archetypes and a set of 15,034 non-calcareous vineyard soils for 4 agricultural scenarios. Cu ranked as the most impacting substance for potential freshwater ecotoxicity among the 12 studied active ingredients. With the inclusion of spatial differentiation, Cu toxicity potentials vary 3 orders of magnitude, making variation according to water archetypes potentially relevant. In the case of non-calcareous soils ecotoxicity characterization, the variability of Cu impacts in different receiving environments is about 2 orders of magnitude. Our results show that Cu potential toxicity depends mainly on its capacity to interact with the emission site, and the dynamics of this interaction (speciation). These results represent a better approximation to understand Cu
potential toxicity impact profiles, assisting decision makers to better understand copper behavior concerning the receiving environment and therefore how restrictions on the use of copper-based fungicides should be considered in relation to the emission site.

Modeling rational, psychological, and social behavior toward diffusion of new technology using agent-based simulation: the case of the public utility jeeps,

In most developing countries, over-aged vehicles play a significant role in energy demand and air pollution, which make the transportation sector a suitable choice for investigating opportunities to mitigate climate change. Apparently, people heterogeneity, social influence, and network configuration affect diffusion of innovation. This study presents an agent-based model (ABM) to simulate the rational decision-making, psychological behavior, and social interaction of people to explore their reaction to policy scenarios toward adopting technological changes over time. The aim of model is to assist policymakers for energy and environmental policy design based on consumers’ behavior. The jeepney owners in the old public utility jeeps (PUJ) fleet in Metro Manila are chosen as case study to prove the applicability of the model. The results show that rational, psychological, and social interaction of owners could not lead to diffusion of technology without intervention of policy instruments. However, by implementing incentive-based policies, the entire jeepney fleet could be renovated before the end of simulation horizon and the government could launch a 5-year plan to combat pollution of the fleet. The model could be applied to evaluate and prioritize strategies for reducing the future energy requirements and emissions in other fleets and regions.
Modelling production-consumption flows of goods in Europe: the trade model within Transtools3

The paper presents a new model for trade flows in Europe that is integrated with a logistics model for transport chain choice through Logsum variables. Logsums measure accessibility across an entire multi-modal logistical chain, and are calculated from a logistics model that has been estimated on disaggregated micro data and then used as an input variable in the trade model. Using Logsums in a trade model is new in applied large-scale freight models, where previous models have simply relied on the distance (e.g. crow-fly) between zones. This linkage of accessibility to the trade model makes it possible to evaluate how changes in policies on transport costs and changes in multi-modal networks will influence trade patterns. As an example the paper presents outcomes for a European-wide truck tolling scenario, which showcases to which extent trade is influenced by such a policy. The paper discusses how such a complex model can be estimated and considers the choice of mathematical formulation and the link between the trade model and logistics model. In the outcomes for the tolling scenario we decompose the total effects into effects from the trade model and effects from the logistics model.

Modelling the influence of changing climate in present and future marine eutrophication impacts from spring barley production

Nitrate concentration and runoff are site-specific and driven by climatic factors and crop management. As such, nitrate emissions may increase in the future due to climate change, affecting the marine eutrophication mechanism. In this context, and considering the case of spring barley production in Denmark, the paper has two objectives: (i) to estimate the present and future marine eutrophication impacts by combining a novel Life Cycle Impact Assessment (LCIA) modelling approach with a quantification of the effects of climate change on its parameterisation, and (ii) to discuss the implications of different normalisation references when comparing future Life Cycle Assessment (LCA) scenarios with current production systems. A parameterised characterisation model was developed to gauge the influence of future climate-driven pressures on the marine eutrophication impact pathway. Spatial differentiation was added to the resulting ‘present’ and ‘future’ characterisation factors (CFs) and calculated for the Baltic and North Sea. The temporal variability of both midpoint normalised impact scores and damage scores reflect a 34% and 28% increase of the CFs in the North Sea and Baltic Sea, respectively. The temporal variability is mainly explained by CF variation and increasing future nitrogen flows. The marine eutrophication indicator scores at both midpoint and damage levels suggest that the differentiation of impacts to various receiving (and potentially perturbed) ecosystems is relevant. Damage scores are quantified with a factor 2.5 and 2.3 differentiation between the Baltic (higher) and North Seas (lower) for the present and future scenarios, respectively. The comparison of the normalisation methods, either based on total annual impacts (domestic inventory of background interventions), on ecological carrying capacity, or on the presently proposed method, point to the value of adding spatial differentiation to LCIA models. The inclusion of time variation and spatial differentiation in characterisation modelling of marine eutrophication and the identification of a paucity of adequate inventory data for future scenario analysis constitute the main outcomes of this study. Further research should aim at reducing the uncertainty of the parameterisation under future conditions and strengthening emissions projections.
Modularising design processes of façades in Denmark: re-exploring the use of design structure matrix

Modularity has shown great potential in the manufacturing industry, reducing order lead time and creating variety with limited resources. In the construction industry, the implementation of modularity has been limited to off-site production (OSP). The construction design process incorporates a substantial number of disciplines and stakeholders. Moreover, in the application OSP, the design phase is critical due to the necessity of freezing the design early in the process. This study explores the opportunities for optimising the design processes for OSP through the application of modularity. Framed by a large general contractor, the research is based on a case study of façade design, which is representative of design processes for OSP. Research is based on a theoretical framing within design management and modularity, combined with empirical material from 20 interviews and a two-hour-long workshop with a cross-functional design team. The findings were that (1) the application of a modularity perspective in design has the advantage of accelerating the execution process, as the workload and coordination are transferred to the design process, which, in turn, requires enhanced design management. (2) The design structure matrix (DSM), an approach for operationalising modularity theory, is a promising tool for planning and scheduling complex design processes. The DSM method successfully enabled the identification of dependencies and interfaces between the crucial cross-organisational design activities that are related to the façade design process. (3) The developed process modules are helpful to visualise and execute the process for both project participants and managers.

Myopic loss aversion in the response of electric vehicle owners to the scheduling and pricing of vehicle charging

Upward expectations of future electric vehicle (EV) growth pose the question about the future load on the electricity grid. While existing literature on EV charging demand management has focused on technical aspects and considered EV-owners as utility maximizers, this study proposes a behavioural model incorporating psychological aspects relevant to EV-owners facing charging decisions and interacting with the supplier. The behavioural model represents utility maximization under myopic loss aversion (MLA) within an ultimatum game (UG) framework where the two players are the EV-owner and the electricity supplier. Experimental economics allowed testing the validity of the behavioural model by designing three experiments where a potential EV-owner faces three decisions (i.e., to postpone EV charging to off-peak periods for a discount proposed by the supplier, the amount of discount to request for off-peak charging at times decided by the supplier, and the amount of discount to accept for supplier-controlled charging) under two contract durations (i.e., short-term, long-term). Findings from the experiments show that indeed potential EV-owners perform charging decisions while being affected by MLA resulting from monetary considerations and the UG participation, and that presenting long-term contracts help potential EV-owners to curtail MLA behaviour and minimise cost even though the assumption of utility maximization is violated. The growing share of variable renewable energy (VRE) is expected to increase the need for flexibility in the energy systems in many countries. VRE generation is highly variable because it is determined by weather conditions. The geographical distribution of installed wind generation affects the probability distribution (PD) of the aggregate generation, including the probabilities of very low or high generation. A combined modelling of wind and solar power has been presented. Here, a combined analysis of wind and solar power in multiple Nordic and Baltic countries is presented. The analysed scenarios are the baseline scenarios from.

Variable renewable energy generation is analysed using the CorWind tool developed at DTU Wind Energy. In addition to analysing VRE generation, the variability of net load (electricity consumption subtracted by VRE generation) is analysed. Compared to 2014, the relative variability in VRE generation decreases in the future scenarios, as the overall geographical dispersion of the installed VRE generation increases. The correlation between solar and wind generation is generally slightly negative, which can reduce the variability of the aggregate generation compared to only having wind generation in the VRE generation mix (however, the installed solar generation capacities in the analysed scenarios are low, so this effect is small).

Figure 1 shows the probability distribution functions (PDFs) of the aggregate net load in the different scenarios. The standard deviation (STD) of the hourly net load increases notably in 2050 (22% higher than in 2014). At the same time, the expected value of the net load decreases. Thus, there will be less energy to be generated by the other generation types, such as hydro power, while the need for flexibility increases. Alternatively, the variability in the net load can be managed by demand-side response, transmission of power to or from surrounding countries or by storing energy.

With more VRE generation installed, the probability of very high net load decreases (as some VRE generation is usually available during peak consumption). However, there is always some probability that the aggregate VRE generation is zero, so the highest possible net load is determined by peak consumption. This may raise questions considering the incentives to hold enough other generation capacity to meet the rare peak net load.

Compared to the hourly ramp rates in consumption, the increasing VRE generation increases the ramp rates in the aggregate net load only moderately in the future scenarios; STD of the net load ramp rate in 2050 is expected to be 14% higher than in 2014. However, while ramp rates in consumption happen usually at well-known times (i.e., ramping up in working day mornings), the hourly changes in VRE generation are less predictable.

Neural network-based survey analysis of risk management practices in new product development
The current study investigates the applicability of Artificial Neural Networks (ANNs) to analyse survey data on the effectiveness of risk management practices in product development (PD) projects, and its ability to forecast project outcomes. Moreover, this study presents the relations between risk management factors affecting the success of a PD project, such as cost. ANNs were chosen due to the fact that hidden inherent relations can be revealed through this type of quantitative analysis. Flexibility in terms of analysis and adaptability on the given dataset are the great advantages of Artificial Neural Networks. Dataset used is a filtered survey of 291 product development programs. Answers of this survey are used as training input and target output, in pattern recognition two-layer feedforward networks, using various transfer functions. Using this method, relations among 6 project practices and 13 outcome metrics were revealed. Results of this analysis are compared with existent results made through statistical analysis in prior work of one of the authors. Future investigation is needed in order to tackle the lack of data and create an easy to use platform for industrial use.

New insights into the stochastic ray production frontier
The stochastic ray production frontier was developed as an alternative to the traditional output distance function to model production processes with multiple inputs and multiple outputs. Its main advantage over the traditional approach is that it can be used when some output quantities of some observations are zero. In this paper, we briefly discuss—and partly refute—a few existing criticisms of the stochastic ray production frontier. Furthermore, we discuss some shortcomings of the stochastic ray production frontier that have not yet been addressed in the literature and that we consider more important than the existing criticisms: taking logarithms of the polar coordinate angles, non-invariance to units of measurement, and ordering of the outputs. We also give some practical advice on how to address the newly raised issues.

New vigour involving statisticians to overcome ensemble fatigue

Climate simulation data comprise a range of different phenomena with complex and interacting processes. Yet our understanding of the climate is incomplete despite the huge volumes of data, of which only a small fraction has been explored, and many questions remain, particularly those on the character and origin of uncertainties associated with model simulations and how further modelling efforts can improve understanding. Here, we question whether climate model information could be used more effectively and how so-called 'ensembles of opportunity' should be interpreted. Statisticians can contribute substantially to designing 'smarter' ensemble experiments, improving the distillation of information from ensembles, and helping interpret the relative merits of additional simulations. Future progress may be enhanced by increasing collaborations with statisticians.

Normalisation and weighting in life cycle assessment: quo vadis?
Purpose: Building on the rhetoric question "quo vadis?" (literally "Where are you going?"), this article critically investigates the state of the art of normalisation and weighting approaches within life cycle assessment. It aims at identifying purposes,
current practises, pros and cons, as well as research gaps in normalisation and weighting. Based on this information, the article wants to provide guidance to developers and practitioners. The underlying work was conducted under the umbrella of the UNEP-SETAC Life Cycle Initiative, Task Force on Cross-Cutting issues in life cycle impact assessment (LCIA).

Methods: The empirical work consisted in (i) an online survey to investigate the perception of the LCA community regarding the scientific quality and current practice concerning normalisation and weighting; (ii) a classification followed by systematic expert-based assessment of existing methods for normalisation and weighting according to a set of five criteria: scientific robustness, documentation, coverage, uncertainty and complexity. Results and discussion: The survey results showed that normalised results and weighting scores are perceived as relevant for decision-making, but further development is needed to improve uncertainty and robustness. The classification and systematic assessment of methods allowed for the identification of specific advantages and limitations. Conclusions: Based on the results, recommendations are provided to practitioners that desire to apply normalisation and weighting as well as to developers of the underlying methods.

This report introduces the set of basic data to define scenarios with realistic yet ambitious targets for offshore wind power development in the North Sea to be used in the NSON-DK project. The assumptions are in line with those of IEA for a two degree temperature increase scenario and correspond with a strong recovering of coal and crude oil prices, and a pronounced increase of CO2 prices from 2020. For the countries around the North Sea that are considered, the evolution of electricity demand is projected to be strongly impacted by aggressive energy efficiency policies that lead in total to stagnating consumption despite substantial electric vehicle up-take. To the contrary, Denmark is assumed to substantially increase its consumption, i.e. by 14% from 2020 to 2050. However, the Danish electricity system is looking forward to a decommissioning of the remaining coal fired power plants towards the mid of the century and replacing these capacities essentially with natural gas power plants. In Belgium, and Germany nuclear power plants are expected to be phased-out by 2035, with Sweden following this policy by 2050. Moreover, the economic outlook for nuclear in the other countries is also weak mainly due to pronounced competition from fluctuating renewable energies. In regard to wind energy, for Denmark it is suggested that onshore installations are not increased significantly after 2030. By contrast, a major increase in offshore wind energy is assumed. Corresponding with these offshore and onshore wind power developments, the proposed NSON-DK scenario projects at least 8 TWh higher expected annual wind generation for Denmark. Given the pronounced increases of offshore wind farms, the installations are expected to form significant clusters from 2030 onwards with particularly strong developments in the British Hornsea and on the Dogger Bank.

On the boundary between economy and environment in life cycle assessment

Purpose: We investigate how the boundary between product systems and their environment has been delineated in life cycle assessment and question the usefulness and ontological relevance of a strict division between the two. Methods: We consider flows, activities and impacts as general terms applicable to both product systems and their environment and propose that the ontologically relevant boundary is between the flows that are modelled as inputs to other activities (economic or environmental) and the flows that are regarded as final impacts, in the sense that no further feedback into the product system is considered before these impacts are applied in decision-making. Using this conceptual model, we contrast the traditional mathematical calculation of the life cycle impacts with a new, simpler computational structure where the life cycle impacts are calculated directly as part of the Leontief inverse, treating product flows and environmental flows in parallel, without the need to consider any boundary between economic and environmental activities. Results and discussion: Our theoretical outline and the numerical example demonstrate that the distinctions and boundaries between product systems and their environment are unnecessary and in some cases obstructive from the perspective of impact assessment, and can therefore be ignored or chosen freely to reflect meaningful distinctions of specific life cycle assessment (LCA) studies. We show that our proposed computational structure is backwards compatible with the current practice of LCA modelling, while allowing inclusion of feedback loops both from the environment to the economy and internally between different impact categories in the impact assessment. Conclusions: Our proposed computational structure for LCA facilitates consistent, explicit and transparent modelling of the feedback loops between environment and the economy and between different environmental mechanisms. The explicit and transparent modelling, combining economic and environmental information in a common computational structure, facilitates data exchange and re-use between different academic fields.

On the Circular Supply Chain's Impact on Revenue Growth for Manufacturers of Assembled Industrial Products – a Conceptual Development Approach

Materials scarcity, legislative compliance, and cost savings opportunities drive firms to take back used products from their customers for reuse, recovery, and recycling. For this purpose, firms implement circular supply chains. Although academia has given circular supply chain related topics considerable attention since the 1990s, the relationship between the circular supply chain and the firm’s revenue growth remains under-researched. Using revenue growth theory, this study examines how the use of circular supply chains can grow the revenue of manufacturers of assembled industrial products (e.g. process equipment and engines). Findings show that the circular supply chain can increase revenue streams from the firm’s existing markets, create market opportunities in new geographies, and provide access to market segments un-addressable with the firm’s new products. The paper adds to understanding of the circular supply chain and provides research suggestions into the revenue potential inherent in circular supply chains.

On the Impact of using Mixed Integer Programming Techniques on Real-world Offshore Wind Parks

Wind power is a leading technology in the transition to sustainable energy. Being a new and still more competitive field, it is of major interest to investigate new techniques to solve the design challenges involved. In this paper, we consider optimization of the inter-array cable routing for offshore wind farms, taking power losses into account. Since energy losses in a cable depend on the load (i.e. wind), cable losses are estimated by considering a possibly large number wind scenarios. In order to deal with different wind scenarios efficiently we used a precomputing strategy. The resulting optimization problem considers two objectives: minimizing immediate costs (CAPEX) and minimizing costs due to power losses. This makes it possible to perform various what-if analyses to evaluate the impact of different preferences to CAPEX versus reduction of power losses. Thanks to the close collaboration with a leading energy company, we have been able to report results on a set of real-world instances, based on six existing wind parks, studying the economical impact of considering power losses in the cable routing design phase.

On the Scheduling of Operating Theatres by using a Simulation-based Markov Decision Process

Daily scheduling of surgical operations is a complicated and recurrent problem in the literature on health care optimization. In this study, we present an often overlooked approach to this problem that incorporates a rolling and overlapping planning horizon. The basis of our modeling approach is a Markov decision process, where patients are allocated to a date and room on a daily basis. By assuming that both state and action space is only partially observable, we apply our model in an
on-line scheme known as rollout, where actions are constructed using a heuristic search method. Our objective in this study is to test the potential of using this modeling approach on the resulting hospital costs, and number of patients that are outsourced to avoid violation of capacity constraints. Using data from a Danish hospital case, we find a distinct improvement in performance when compared to a close-to-manual scheduling policy. Further analysis shows that quite similar performance can be obtained by using a heuristic and myopic approach to the problem.

Optimal Scheduling of Railway Track Possessions in Large-Scale Projects with Multiple Construction Works
This paper addresses the railway track possession scheduling problem (RTPSP), where a large-scale railway infrastructure project consisting of multiple construction works is to be planned. The RTPSP is to determine when to perform the construction works and in which track possessions while satisfying different operational constraints and minimizing the total construction cost. To find an optimal solution of the RTPSP, this paper proposes an approach that, first, transfers the nominal market prices into track-possession-based real prices, and then generates a schedule of the construction works by solving a mixed-integer linear-programming model for the given track blocking proposal. The proposed approach is tested on a real-life case study from the Danish railway infrastructure manager. The results show that, in 2 h of computing time, the approach is able to provide solutions that are within 0.37% of the optimal one for six different blocking proposals and two alternative construction providers, so it can be used as an effective support tool in the primary planning stage to suggest preferable track possessions within the existing railway services. Optimization in liner shipping

Seaborne trade is the lynchpin in almost every international supply chain, and about 90% of non-bulk cargo worldwide is transported by container. In this survey we give an overview of data-driven optimization problems in liner shipping. Research in liner shipping is motivated by a need for handling still more complex decision problems, based on big data sets and going across several organizational entities. Moreover, liner shipping optimization problems are pushing the limits of optimization methods, creating a new breeding ground for advanced modelling and solution methods. Starting from liner shipping network design, we consider the problem of container routing and speed optimization. Next, we consider empty container repositioning and stowage planning as well as disruption management. In addition, the problem of bunker purchasing is considered in depth. In each section we give a clear problem description, bring an overview of the existing literature, and go in depth with a specific model that somehow is essential for the problem. We conclude the survey by giving an introduction to the public benchmark instances LINER-LIB. Finally, we discuss future challenges and give directions for further research.

Optimization methods for the Train Unit Shunting Problem

We consider the Train Unit Shunting Problem, an important planning problem for passenger railway operators. This problem entails assigning train units from shunting yards to scheduled train services in such a way that the resulting operations are without conflicts. The problem arises at every shunting yard in the railway network and involves matching train units to arriving and departing train services as well as assigning the selected matchings to appropriate shunting yard tracks. We present an extensive comparison benchmark of multiple solution approaches for this problem, some of which are novel. In particular, we develop a constraint programming formulation, a column generation approach, and a randomized greedy heuristic. We compare and benchmark these approaches with two existing methods, a mixed integer linear program and a two-stage heuristic. The benchmark contains multiple real-life instances provided by the Danish State Railways (DSB) and Netherlands Railways (NS). The results highlight the strengths and weaknesses of the considered approaches.

Optimization of a flexible multi-generation system based on wood chip gasification and methanol production

Flexible multi-generation systems (FMGs) consist of integrated and flexibly operated facilities that provide multiple links between the different sectors of the energy system. The present study treated the design optimization of a conceptual FMG which integrated a methanol-producing biorefinery with an existing combined heat and power (CHP) unit and industrial energy utility supply in the Danish city of Horsens. The objective was to optimize economic performance and minimize total CO₂ emission of the FMG while it was required to meet the local district heating demand plus the thermal utility demand of the butchery. The design optimization considered: Selection, dimensioning, location and integration of processes; operation optimization with respect to both hourly variations in operating conditions over the year as well as expected long term energy system development; and uncertainty analysis considering both investment costs and operating conditions. Applying a previously developed FMG design methodology, scalable models of the considered processes were developed and the system design was optimized with respect to hourly operation over the period 2015–2035. The optimal design with respect to both economic and environmental performance involved a maximum-sized biorefinery located next to local industry rather than in connection with the existing CHP unit. As the local industry energy demands were limited when compared to the biorefinery dimensions considered, process integration synergies were found to be marginal when compared to the economic and environmental impact of the biorefinery for the present case. Assessing the impact of uncertainties on the estimated FMG performances, the net present value (NPV) of the optimal design was estimated to vary within the range 252.5–1471.6 M€ in response to changes of ± 25% in investment costs and methanol price, and considering two different electricity price scenarios. In addition, a change in the interest rate from 5% to 20% was found to reduce the lower bound of the NPV to 181.3 M€ for reference operating conditions. The results suggest that the applied interest rate and operating conditions, in particular the methanol price, would have a much higher...
impact on the economic performance of the designs than corresponding uncertainties in investment costs. In addition, the study outcomes emphasize the importance of including systematic uncertainty analysis in the design optimization of FMG concepts.

Optimization of hospital ward resources with patient relocation using Markov chain modeling

Overcrowding of hospital wards is a well-known and often revisited problem in the literature, yet it appears in many different variations. In this study, we present a mathematical model to solve the problem of ensuring sufficient beds to hospital wards by re-distributing beds that are already available to the hospital. Patient flow is modeled using a homogeneous continuous-time Markov chain and optimization is conducted using a local search heuristic. Our model accounts for patient relocation, which has not been done analytically in literature with similar scope. The study objective is to ensure that patient occupancy is reflected by our Markov chain model, and that a local optimum can be derived within a reasonable runtime. Using a Danish hospital as our case study, the Markov chain model is statistically found to reflect occupancy of hospital beds by patients as a function of how hospital beds are distributed. Furthermore, our heuristic is found to efficiently derive the optimal solution. Applying our model to the hospital case, we found that relocation of daily arrivals can be reduced by 11.7% by re-distributing beds that are already available to the hospital.
Optimizing the supply chain of biomass and biogas for a single plant considering mass and energy losses

The share of renewable energy in the Danish energy sector is increasing and the goal is that biogas production should reach a production level of 17 petajoules (PJ) in 2020 according to the Danish Energy Agency. However, this goal is currently not reachable due to lack of investments in biogas plants. In this paper, a mixed integer programming (MIP) model for finding the optimal production and investment plan for a biogas supply chain is presented to ensure better economy for the full chain hopefully stimulating future investments in biogas. The model makes use of step-wise linear functions to represent capital and operational expenditures at the biogas plant; considers the chain from the farmer to the end market; and includes changes of mass and energy content along the chain by modeling the losses and gains for all processes in the chain. Biomass inputs are scheduled on a weekly basis whereas energy outputs are scheduled on an hourly basis to better capture the changes of energy prices and potentially take advantage of these changes. The model is tested on a case study with co-digestion of straw, sugar beet and manure, considering natural gas, heat, and electricity as end products. The model finds a production and investment plan for a predefined location of the plant within half an hour of central processing unit (CPU) time. The resulting project turns out to be profitable and gives a production plan for each process, which underlines the possibilities of optimizing the processes in a biogas project.
Optimizing wind farm cable routing considering power losses

Wind energy is the fastest growing source of renewable energy, but as wind farms are getting larger and more remotely located, installation and infrastructure costs are rising. It is estimated that the expenses for electrical infrastructure account for 15-30% of the overall initial costs, hence it is important to optimize o shore inter-array cable routing. The routing should connect all turbines to one (or more) o shore sub-station(s) while respecting cable capacities, no-cross restrictions, connection-limits at the substation, and obstacles at the site. The objective is to minimize both the capital that must be spent immediately in cable and installation costs, and the future reduced revenues due to power losses. The latter goal has not been addressed in previous work. We present a Mixed-Integer Linear Programming approach to optimize the routing using both exact and math-heuristic methods. In the power losses computation, wind scenarios are handled eciently as part of the preprocessing, resulting in a MIP model of only slightly larger size. A library of real-life instances is introduced and made publicly available for benchmarking. Computational results on this testbed show the viability of our methods, proving that savings in the order of millions of Euro can be achieved.

This paper reviews path-creation processes in road transport systems in the Nordic countries: e-mobility in Denmark, hydrogen and fuel-cell electrical vehicles in Norway, and advanced biofuels in Finland and Sweden. The study builds on the path creation literature, which seeks to explain the emergence of new technological pathways. Drawing on recent insights concerning the differences between design- and manufacturing-intensive technologies, the paper analyses the influence of technological characteristics on path creation processes. The case comparison indicates that technological characteristics seem to have greater influence on the content of activities in the later phase rather than the early phase of path creation processes. The analysis also emphasises that barriers to path creation processes differ depending on technological characteristics. This highlights the importance of considering technological characteristics in energy and transport policies.
Industry constitutes a substantial share of the energy and fuel consumption in energy systems. Types and patterns of usage within different industrial sectors are diverse. In this paper, we illustrate the energy and fuel use in Danish industry by 24 end-uses and 20 fuels and provide hourly profiles for electricity, space and process heating. The heat profiles are based on measured natural gas consumption. While seasonal patterns are predominant for space heating, process heating and electricity consumption are found to follow sector-related activities on a temporal scale. Building on this data analysis and profile generation we describe an approach to implement this level of detail in an integrated energy system model. This work is part of assessing the role of industry in the future Danish energy system.

Policies for system change: the transition to the bioeconomy

Over the past 10-15 years the bioeconomy has increased in importance and has been promoted as a possible contribution to address important societal challenges such as climate change, food security, and global health issues. It is argued that the development towards a circular bioeconomy can be characterised as a system change as it requires fundamental changes in both production and consumption systems (Coenen, Hansen, and Rekers 2015; Bugge, Hansen, and Klitkou 2016; Scordato, Bugge, and Fevolden 2017). However, even if governments in many countries have started to introduce policies addressing grand societal challenges, it remains unclear how policies can be implemented to achieve determined goals, and also how such policies can be understood in relation to existing policies (Kuhlmann and Rip 2014; OECD 2015; Schot and Steinmueller 2016). Still, we know very little about the extent to which policies are in fact giving sufficient importance to transformative failures (vis-à-vis market and structural failures). Also, to the extent that transformative failures are given attention in bioeconomy policies, we don’t know whether this is consistent in the policy mix or only in terms of formulating visions.

Potentials and limitations of footprints for gauging environmental sustainability

To address the sustainability challenge, a large variety of footprints, aiming at capturing specific impacts of human activities on natural environment, have emerged. But, how do they fit into our addressing of environmental sustainability? Here, we build on a critical literature review to (1) provide an overview of existing footprints; (2) define their roles; (3) position them within the broad spectrum of known environmental problems and control variables of the planetary boundaries; and (4) argue for the need of consistent thresholds to benchmark footprint scores against absolute
sustainability measures defined using science-based sustainability targets. Potentials, limitations and research needs are highlighted along these four points.

**Predicting the Potential Market for Electric Vehicles**
Forecasting the potential demand for electric vehicles is a challenging task. Because most studies for new technologies rely on stated preference (SP) data, market share predictions will reflect shares in the SP data and not in the real market. Moreover, typical disaggregate demand models are suitable to forecast demand in relatively stable markets, but show limitations in the case of innovations. When predicting the market for new products it is crucial to account for the role played by innovation and how it penetrates the new market over time through a diffusion process. However, typical diffusion models in marketing research use fairly simple demand models. In this paper we discuss the problem of predicting market shares for new products and suggest a method that combines advanced choice models with a diffusion model to take into account that new products often need time to gain a significant market share. We have the advantage of a relatively unique databank where respondents were submitted to the same stated choice experiment before and after experiencing an electric vehicle. Results show that typical choice models forecast a demand that is too restrictive in the long period. Accounting for the diffusion effect, instead allows predicting the usual slow penetration of a new product in the initial years after product launch and a faster market share increase after diffusion takes place.

Prerequisites for Successful Strategic Partnerships for Sustainable Building Renovation

The purpose of this paper is to identify the prerequisites for establishing successful strategic partnerships in relation to renovating buildings sustainably. Establishing strategic partnerships is in the paper seen as a potential way to make building renovation more sustainable in Denmark particularly in terms of reducing energy consumption and use of resources and increase productivity. However, until now we have only had a limited number of such partnerships implemented and the few examples that do exist, mostly concern the construction of new buildings. The paper is based on an investigation and analysis of strategic partnerships models as well as typical processes used in building renovation. Experiences from development of new strategic partnerships have particularly been found in the UK and Sweden. Based on two workshops with practitioners representing the whole value chain in the construction industry and analyses of two exemplary cases the paper suggests prerequisites for establishing successful strategic partnerships for sustainable building renovation. The results show that strategic partnerships are collaborations set up between two or more organizations that remain independent with the purpose of obtaining a goal of mutual and high priority based on a binding commitment and a long term perspective by a consecutive number of projects. An essential prerequisite for most of the identified challenges in building renovation processes is stable project partners. Framework agreements is a way to legally establish collaboration with more stable project partners, but it is also in itself an important prerequisite to target challenges related to tender, competition and an extreme focus on lowest price.

Probabilistic Modeling and Visualization for Bankruptcy Prediction

In accounting and finance domains, bankruptcy prediction is of great utility for all of the economic stakeholders. The challenge of accurate assessment of business failure prediction, specially under scenarios of financial crisis, is known to be complicated. Although there have been many successful studies on bankruptcy detection, seldom probabilistic approaches were carried out. In this paper we assume a probabilistic point-of-view by applying Gaussian Processes (GP) in the context of bankruptcy prediction, comparing it against the Support Vector Machines (SVM) and the Logistic Regression (LR). Using real-world bankruptcy data, an in-depth analysis is conducted showing that, in addition to a probabilistic interpretation, the GP can effectively improve the bankruptcy prediction performance with high accuracy when compared to the other approaches. We additionally generate a complete graphical visualization to improve our understanding of the different attained performances, effectively compiling all the conducted experiments in a meaningful way. We complete our study with an entropy-based analysis that highlights the uncertainty handling properties provided by the GP, crucial for prediction tasks under extremely competitive and volatile business environments.

Manufacturing in the twenty-first century has been wrought with the struggle to satisfy the rising demand for greater product variety and more complex products while still maintaining efficient manufacturing operations. However, the literature lacks an overview of which operational performance measures are most affected by increased variety and complexity. This study presents a systematic literature review of the recent scholarly literature on variety, complexity and manufacturing operational performance (MOP). Results show that product variety has a consistently negative relationship with MOP across different time, cost, quality and flexibility measures while product complexity lacks evidence of strong relationships with MOP measures.

Prosumers and smart grid technologies in Denmark: developing user competences in smart grid households
This paper explores and describes resident’s experiences from a smart grid project that involved 20 households in a rural area in Denmark and ran from 2014 to 2015. The study is based on qualitative data from the participating households, collected 6, 12 and 18 months after the start of the intervention. Drawing on theories of social practice and the three intertwined elements of a practice: competences, images and materials, the paper contributes with an in-depth analysis of a complex intervention, focusing on how the participants changed energy practices as a result of the installed smart grid technologies. Long-term studies on such comprehensive energy interventions and derived changes in domestic energy practices are exceptional. The results show that people relate to their natural environment in new ways and construct new practices according to the movements of the sun; that they gradually become skilled practitioners and prosumers; and that they also increase consumption and develop expectations towards the energy company, requesting better dialogue on energy consumption and control. The paper concludes with reflections and suggestions on how findings may be relevant to policy and research in the area.

Railway capacity and expansion analysis using time discretized paths

When making investments in railway infrastructure it is important to be able to identify the limits for freight transportation in order to not only use the infrastructure in the best possible way, but to also guide future capacity investments. This paper presents a model to assess the capacity of railway freight transportation on a long term strategic level. The model uses an hourly time discretization and analyses the impact of railway network expansions based on future demand forecasts. It provides an optimal macroscopic freight train schedule and can indicate the time and place of any congestion. In addition, two expansions of the primary model are developed. The first can be used to determine the minimal number of expansions needed to ensure all freight can be feasibly routed, while the second can be used to schedule freight trains at hours not congested by passenger trains using variable penalties for the different passenger busy time slots. As part of a European Union project, all models are applied to a realistic case study that focuses on analyzing the capacity of railway network, in Denmark and Southern Sweden using demand forecasts for 2030. Results suggest that informative solutions can be found quickly with the proposed approach.

The project was partly funded by the EU-project EWTC-II.

Realistic Creativity Training for Innovation Practitioners: The Know-Recognize-React Model
As creativity becomes increasingly recognized as important raw material for innovation, the importance of identifying ways to increase practitioners' creativity through rigorously designed creativity training programs is highlighted. Therefore we set out to design a creativity training program specifically developed for innovation practitioners. Our aim, in addition to making a program based on a rigorous scientific foundation, was to develop a program which would be relevant for practitioners, theoretically sound, as well as realistic for real-world context. This we accomplished, in part, through the transdisciplinary study described in this paper. Co-creation was employed as a method to ensure the three layers of focus would be taken into consideration. The result is a program called Creative Awareness Training which is based on the new Know-Recognize-React model.

Reflections on experience with the global network on energy for sustainable development as a South–South global knowledge network

The Global Network on Energy for Sustainable Development (GNESD) was an initiative launched at the 2002 World Summit on Sustainable Development to support the agenda for increased access to clean energy, as a key contribution to sustainable development. In addition to understanding how the Network was established, how it sustained its relations and organised its activities across borders, we contribute to the debate on global networks by introducing the concept of 'outcomes', as a means to understand the extent to which, and how, the Network was able to influence change within the participating countries. We conclude from the analysis that although there are numerous observable and verifiable outcomes, these were achieved in a rather unsystematic manner especially during the early years, and in a more structured and targeted manner during the last 5 years of the Network. To a great extent this reflects the output-focus that was prevalent within UNEP, and other similar organisations, at the time the Network was established. It also reflects the well-known structural challenge faced by many epistemic communities, where the extent of their influence reflects the extent to which they are embedded within evolving power structures. Finally, we offer a number of specific recommendations for future networks, based on the GNESD experience.
Regression-based Online Anomaly Detection for Smart Grid Data

With the widely used smart meters in the energy sector, anomaly detection becomes a crucial mean to study the unusual consumption behaviors of customers, and to discover unexpected events of using energy promptly. Detecting consumption anomalies is, essentially, a real-time big data analytics problem, which does data mining on a large amount of parallel data streams from smart meters. In this paper, we propose a supervised learning and statistical-based anomaly detection method, and implement a Lambda system using the in-memory distributed computing framework, Spark and its extension Spark Streaming. The system supports not only iterative detection model refreshment from scalable data sets, but also real-time detection on scalable live data streams. This paper empirically evaluates the system and the detection algorithm, and the results show the effectiveness and the scalability of the proposed lambda detection system.
Regulatory barriers for activating flexibility in the Nordic-Baltic electricity market

The rapid growth of variable renewable energy (VRE) and the expected decrease of conventional generation capacities will generate more flexibility needs in power systems and require flexibility resources to be activated. Flexibility potentials do exist, whether they refer to installed generation, load adjustment or to a greater coupling to other energy sectors. In this paper, we identify the framework conditions that influence the provision of VRE-friendly flexibility in the Nordic and Baltic electricity sector, i.e., the market and regulatory settings that act as drivers or barriers to flexibility. We find that the most restrictive barriers against flexibility are emitted by public authorities as part of broader policy strategies. Overall, we find that current regulatory and market framework conditions do not hinder flexibility. However, despite that, flexibility remains limited due to a lack of coherent instruments intended to both the demand and supply-side to effectively act flexibly.

Relational uncertainty in service dyads
Purpose: Relational uncertainty determines how relationships develop because it enables the building of trust and commitment. However, relational uncertainty has not been explored in an inter-organisational setting. This paper investigates how organisations experience relational uncertainty in service dyads and how they resolve it through suitable organisational responses to increase the level of service quality.

Design/methodology/approach: We apply the overall logic of Organisational Information-Processing Theory (OIPT) and present empirical insights from two industrial case studies collected via semi-structured interviews and secondary data.
Findings: The findings suggest that relational uncertainty is caused by the partner’s unresolved organisational uncertainty, i.e. their lacking capabilities to deliver or receive (parts of) the service. Furthermore, we found that resolving the relational uncertainty increased the functional quality while resolving the partner’s organisational uncertainty increased the technical
quality of the delivered service.

Originality: We make two contributions. First, we introduce relational uncertainty to the OM literature as the inability to predict and explain the actions of a partnering organisation due to a lack of knowledge about their abilities and intentions. Second, we present suitable organisational responses to relational uncertainty and their effect on service quality.

Renewable Energy and Carbon Management in the Cradle-to-Cradle Certification: Limitations and Opportunities

As part of the Cradle to Cradle® (C2C) certification program, the C2C certification criterion, Renewable Energy and Carbon Management (RE&CM), focuses on use of electricity from renewable energy (RE) and direct greenhouse gas offsets in the manufacturing stage and, to a limited extent, on the cradle to gate only at the highest level of certification. The aim of this study is to provide decision makers with a quantified overview of possible limitations of that C2C certification requirement and potential gains by introducing a full lifecycle assessment (LCA) perspective to the scheme. Scenario analysis was used to perform an LCA of an aluminum can system representing different levels of the C2C certification criterion, RE&CM, considering different strategies to achieve 100% RE in the manufacturing stage. The adoption of a broader life cycle RE perspective was considered through the implementation of electricity from renewable sources from cradle to grave. Our results show that compliance with the current RE&CM certification framework offers limited benefits, that is, significant reduction for climate change, but negligible reductions for other environmental impacts (e.g., particulate matter and acidification). However, increasing the share of RE in the primary aluminum production from a full life cycle perspective can greatly increase the environmental benefits brought up by the C2C certification not only for climate change, but also for the broader range of impact categories. In our striving toward environmental sustainability, which often cannot be approximated by climate-change impacts alone, we therefore recommend decision makers in industries to combine the C2C certification with LCA when they define strategies for the selection of RE and raw materials suppliers.
Report Template

To ensure consistent reporting of life cycle assessment (LCA), we provide a report template. The report includes elements of an LCA study as recommended but the ILCD Handbook. Illustrative case study reported according to this template is presented in Chap. 39.

Building a network of hydrogen refuelling stations is essential to develop the hydrogen economy within transport. Additional, hydrogen is regarded a likely key component to store and convert back excess electrical power to secure future energy supply and to improve the quality of biomass-based fuels. Therefore, future hydrogen supply and distribution chains will have to address several objectives. Such a complexity is a challenge for risk assessment and risk management of these chains because of the increasing interactions. Improved methods are needed to assess the supply chain as a whole. The method of "Functional modelling" is discussed in this paper. It will be shown how it could be a basis for other decision support methods for comprehensive risk and sustainability assessments.
Risk Management Challenges in Large-scale Energy PSS

Probabilistic risk management approaches have a long tradition in engineering. A large variety of tools and techniques based on the probabilistic view of risk is available and applied in PSS practice. However, uncertainties that arise due to lack of knowledge and information are still missing adequate representations. We focus on a large-scale energy company in Denmark as one case of current product/servicesystems risk management best practices. We analyze their risk management process and investigate the tools they use in order to support decision making processes within the company. First, we identify the following challenges in the current risk management practices that are in line with literature: (1) current methods are not appropriate for the situations dominated by weak knowledge and information; (2) quality of traditional models in such situations is open to debate; (3) quality of input data and representation of the results to the decision makers play an important role. Second, we introduce a selection of alternative, so-called “post-probabilistic”, risk management methods developed across different scientific fields to cope with uncertainty due to lack of knowledge. Possibilities for overcoming industrial PSS risk management challenges are suggested through application of post-probabilistic methods. We conclude with the discussion on the importance for the field to consider their application.
Road sign comprehension and overload: The role of driving style and need for closure

This study looks at the provision of information via traffic signs and its relation with driving styles, need for closure and socio-economic characteristics of road users. A web-based questionnaire allowed collecting information about traffic signs and road surface markings in 12 traffic locations that were presented in two variations: (i) in the first 6 cases, a first configuration contained information that led to ambiguity about the manoeuvres that were legal and a second configuration added traffic signs to eliminate the ambiguity; (ii) in the second 6 cases, a first configuration presented the road environment without signs and a second configuration added traffic signs to verify information redundancy. Respondents indicated for each location which manoeuvres they deemed legal and how many conflicts they estimated without traffic signs, and safety perception and comfort level improved with the traffic signs. Moreover, respondents reported their socio-economic characteristics and filled two questionnaires about need for closure and driving styles. Completed questionnaires from 753 participants from Hungary with expertise in transport and traffic were analysed via statistical and factor analysis, and results reveal that: (i) road users are heterogeneous in their perception and processing of information, as the number of manoeuvres correctly identified as legal relates to their socio-economic characteristics; (ii) the perception of improvements after the provision of information relates also to the road uses’ socio-economic characteristics and their driving style and need for closure; (iii) different amounts of information are sufficient for different road users not to feel uncertain regarding manoeuvres being legal at a certain traffic location.

Rural electrification through private models: the case of solar-powered mini-grid development in Kenya: Exploring the hybrid nature of private business models and the interplay between new players and existing structures in the Kenyan rural electrification regime

In Sub-Saharan Africa more than 630 million people live without access to electricity. Access to modern energy services like phone-charging, electric lighting, cooling, heating, etc. is an important enabler of social and economic development and human well-being. Renewable energy-based electrification solutions that deliver power through a decentralised mini-grid to village communities have gained in prominence as a supplementary path to achieving universal access in the realisation that, in many developing countries, traditional utility-led grid-electrification efforts will not
succeed in bringing electricity to everyone in the near future. In East Africa, mini-grid development has primarily been driven by NGOs or faith-based organisations. However, recent technological advances like mobile phone payment solutions and drops in solar PV prices are making solar-powered mini-grids a cost-effective alternative to traditional fossil fuel-based solutions like diesel generators in off-grid areas in many countries. This has made rural electrification through mini-grids an interesting area for private-sector firms looking to do mission-driven business in the growing African economies. This, in combination with the broader turn in international development cooperation towards supporting private sector- and market-based solutions to facilitate development goals, makes private sector-driven rural electrification an interesting area for investigation. Against this background, the aim of the research presented in this thesis is to explore the processes behind the emergence of such private-sector engagement, as well as the functioning and effects of specific private-sector models. This research topic is explored through a qualitative multi-case study design to provide context-specific insights into the particularities of the Kenyan mini-grid niche. Dynamics of change in the Kenyan rural electrification regime is investigated through the lens of the multilevel perspective to explore how niche-level actors conduct institutional entrepreneurship to influence existing structures in the rural electrification regime. Furthermore, min-grid firms’ practices are explored to understand how they respond to competing institutional logics made available to them due to their dual social and economic mission.

The research finds that mini-grid firms operating in Kenya contribute to system building in the sense of making private mini-grid development a viable and sustainable alternative to grid-extension in various ways by following different strategies. While some actors are seeking to strengthen the private mini-grid niche by actively seeking to change the ‘rules of the game’ in the broader rural electrification regime through negotiations, advocacy and other forms of institutional work, other actors are following a strategy of increasing cohesion within the niche by building partnerships and generating knowledge and learning. This shows how niches build and grow not only through niche-internal processes, but also through purposeful actor-driven work with the aim to create conditions that allows the niche and the regime to co-exist.

At the firm level, the research finds that mini-grid firms respond differently to the competing demands of the social welfare and economic viability logics available to them. While some firms enact the logic of economic viability as the predominant logic guiding their work, other firms combine and blend the two logics. Each of the two strategies of prioritising or blending is pursued with the conviction that the underlying practices and decisions made manifest in such strategies will benefit these firms. While it is too early to draw conclusions regarding the prospects for the long-term sustainability of these firms, the existence of these various strategies is significant in two ways. First, it suggests that mission-driven enterprises can be differentiated based on the way they enact logics in their work. Secondly, it opens up a path to further research into how each of these strategies may influence the long-term sustainability of these firms.
SafetyBarrierManager, a software tool to perform risk analysis using ARAMIS’s principles
The ARAMIS project resulted in a number of methodologies, dealing with among others: the development of standard fault trees and “bowties”; the identification and classification of safety barriers; and including the quality of safety management into the quantified risk assessment. After conclusion of the ARAMIS project, Risø National Laboratory started developing a tool that could implement these methodologies, leading to SafetyBarrierManager. The tool is based on the principles of “safety-barrier diagrams”, which are very similar to “bowties”, with the possibility of performing quantitative analysis. The tool allows constructing comprehensive fault trees, event trees and safety-barrier diagrams. The tool implements the ARAMIS idea of a set of safety barrier types, to which a number of safety management issues can be linked. By rating the quality of these management issues, the operational probability of failure on demand of the safety barriers can be calculated. The paper will give a short description of the features of the tool, with emphasis on the methodologies that originate from the ARAMIS project. The paper will also address developments and experiences over the last years, which have inspired additional features. This includes a discussion of the use of generic management issues as opposed to concrete safety measures targeted at specific safety barriers, which includes a discussion of the basic philosophy in the ARAMIS methodology of dealing with safety management. The adjustments to the barrier typology is also discussed.

Scheduling EURO-k Conferences
EURO-k conferences are among the largest Operations Research conferences in the world, typically including more than 2000 presentations. As opposed to many other conferences, EURO-k conferences are hierarchically organized, and the conference schedule should reflect this structure to make navigation easier and more logical. In this article we present a scheduling tool that has been developed during the EURO2015 and EURO2016 conferences to schedule the streams, sessions and talks. A schedule is obtained by solving a number of optimization models, each addressing a specific objective. First, areas are assigned to buildings, making sure that related research areas are located close to each other. Next, the goal is to allocate each stream to only one room, and to ensure that the stream consists of a sequence of consecutive time slots. Finally, we optimize the assignment of room sizes. We illustrate the process by showing results from the scheduling of the EURO2016 conference, which took place in Poznan (Poland), July 3–6, 2016.
SciCloud: A Scientific Cloud and Management Platform for Smart City Data

The pervasive use of Internet of Things and smart meter technologies in smart cities increases the complexity of managing the data, due to their sizes, diversity, and privacy issues. This requires an innovative solution to process and manage the data effectively. This paper presents an elastic private scientific cloud, SciCloud, to tackle these grand challenges. SciCloud provides on-demand computing resource provisions, a scalable data management platform and an in-place data analytics environment to support the scientific research using smart city data.

Scientific evidence suggests a changed approach in ergonomic intervention research

Ergonomic interventions have generally been unsuccessful in improving workers' health, with concurrent rationalization efforts negating potentially successful intervention initiatives. We propose the two aims are considered simultaneously, aiming at the joint consideration of competitive performance and work environment in a long-term perspective ("organizational sustainability"). A prerequisite is a high level of dialogue between the different groups of stakeholders, and we argue that the Nordic countries, through high levels of trust and justice (social capital), have unique opportunity to carry out such research. The present authors bring forth the vision of "a Nordic Model for development of more sustainable production systems".

Scope Definition

The scope definition is the second phase of an LCA. It determines what product systems are to be assessed and how this assessment should take place. This chapter teaches how to perform a scope definition. First, important terminology and key concepts of LCA are introduced. Then, the nine items making up a scope definition are elaborately explained: (1) Deliverables, (2) Object of assessment, (3) LCI modelling framework and handling of multifunctional processes, (4) System boundaries and completeness requirements, (5) Representativeness of LCI data, (6) Preparing the basis for the impact assessment, (7) Special requirements for system comparisons, (8) Critical review needs and (9) Planning reporting of results. The instructions relate both to the performance and reporting of a scope definition and are largely based on ILCD.

Scripting, control, and privacy in domestic smart grid technologies: insights from a Danish pilot study

Smart grid research in Denmark has increasingly turned its focus on aggregator trading flexibility achieved by remotely controlling appliances, studying the technologies involved rather than the control. This paper investigates how different types of control were envisioned and designed for a two-year smart grid trial in Denmark with 20 private households. Using the notion of script, processes of in- and de-scription were used to gain insights into perceived and enacted control. Based on empirical data from 26 interviews and three workshops, we show how the in-scription process of control can be characterized as dynamic and includes negotiations between the residents and those responsible for the project. Second, we show how users de-scribe control, and third, we outline the project owners’ reaction to the user’s de-scription of control. The design of the remote control appears to have promoted a reference for ‘passive consumers’ within a smart grid. This design prompts questions about how the users in smart grid development are envisioned and configured using different ideas about control. With current development and the need for additional energy reductions, consumers who invest in photovoltaic solar cells and electric vehicles lose interest in delivering their energy to the system level.
Sectoral dynamics and technological convergence: an evolutionary analysis of eco-innovation in the automotive sector

We know from evolutionary theory that sectoral characteristics are important to innovation. This paper investigates if sectoral characteristics also are important to eco-innovation, a hitherto under-researched theme. We argue that research into possible sectoral patterns in eco-innovation is key to understanding green industrial dynamics and the greening of the economy. This paper investigates to what degree the economy is greening horizontally (sector-wise). Starting with a sectoral case study, we undertake a longitudinal analysis of the breadth and strength of the greening of the automotive sector from 1965 to 2012, focusing on powertrain technologies. The empirical analysis is based on patent data amongst big car producers and focuses on identifying changes in two main aspects: (1) the convergence/divergence of firms’ green strategies and technologies within the automotive sector; and (2) the contribution of alternative key green technological trajectories relative to the dominant design. Our findings indicate that the evolution of relative green patenting has followed a positive, linear growth over the last decades with increasing participation of alternative propulsion technologies and increasing convergence of automakers’ strategies towards a diversified portfolio.

This paper sheds light on some important but underestimated elements of green industrial dynamics: the evolution of firms’ eco-innovation strategies and activities within a sector. While eco-innovation sectoral case studies have taken place before, our analysis is distinct in investigating the rate, direction and extent of eco-innovation in the automotive sector, represented here by the main automakers, in order to identify possibly sectoral-specific patterns in firms’ strategies, as opposed to divergent strategic behaviors, grounded on evolutionary economic theory. We conduct a two-step empirical analysis using patent data from 1965 to 2012. Our findings suggest a process of co-evolution of firms’ strategies and indicate that strong sectoral-specific patterns of eco-innovation are present in this sector from the mid-2000s onwards. For fuel cells technologies, however, we observe the formation of two antagonist patterns. A further econometric analysis is conducted and indicates that the positioning of the firms between these two groups is correlated with the firms’ profit margins and the size of firms’ patent portfolios.
Sensing behaviour in healthcare design

We are entering an era of distributed healthcare that should fit and respond to individual needs, behaviour and lifestyles. Designing such systems is a challenging task that requires continuous information about human behaviour on a large scale, for which pervasive sensing (e.g. using smartphones and wearables) presents exciting opportunities. While mobile sensing approaches are fuelling research in many areas, their use in engineering design remains limited. In this work, we present a collection of common behavioural measures from literature that can be used for a broad range of applications. We focus specifically on activity and location data that can easily be obtained from smartphones or wearables. We further demonstrate how these are applied in healthcare design using an example from dementia care. Comparing a current and proposed scenario exemplifies how integrating sensor-derived information about user behaviour can support the healthcare design goals of personalisation, adaptability and scalability, while emphasising patient quality of life.

Ship routing and scheduling: the cart before the horse conjecture

The literature on ship routing and scheduling has grown substantially over the last few decades, with many papers authored by top experts in this area and examining various versions of the problem. Many publication outlets have hosted these papers, with a broad variety of problem formulations, solution approaches, and application contexts. Equally broad is the range of angles of these papers, spanning the wide field from mostly theoretical analyses, focusing on specific methodological tools, all the way to applied studies, focusing on specific real-world applications. The basic hypothesis of this paper is that we are increasingly seeing papers that are more of theoretical than practical value, and in fact some of them often place the solution approach before real problem definition. As a result of this approach, the connection between these papers and reality is sometimes distant or elusive. To investigate this hypothesis, this paper tries to explain some misconceptions, refers to a limited sample of such papers, and suggests possible ways to rectify this situation in the future.

Simulation of Optimal Decision-Making Under the Impacts of Climate Change

Climate change causes transformations to the conditions of existing agricultural practices appointing farmers to continuously evaluate their agricultural strategies, e.g., towards optimising revenue. In this light, this paper presents a framework for applying Bayesian updating to simulate decision-making, reaction patterns and updating of beliefs among farmers in a developing country, when faced with the complexity of adapting agricultural systems to climate change. We apply the approach to a case study from Ghana, where farmers seek to decide on the most profitable of three agricultural systems (dryland crops, irrigated crops and livestock) by a continuous updating of beliefs relative to realised trajectories of climate (change), represented by projections of temperature and precipitation. The climate data is based on combinations of output from three global/regional climate model combinations and two future scenarios (RCP4.5 and RCP8.5) representing moderate and unsubstantial greenhouse gas reduction policies, respectively. The results indicate that the climate scenario (input) holds a significant influence on the development of beliefs, net revenues and thereby optimal farming practices. Further, despite uncertainties in the underlying net revenue functions, the study shows that when the beliefs of the farmer (decision-maker) opposes the development of the realised climate, the Bayesian methodology allows for simulating an adjustment of such beliefs, when improved information becomes available. The framework can, therefore, help facilitating the optimal choice between agricultural systems considering the influence of climate change.

This study contributes a comparative analysis of 11 Danish smart grid experimental projects with household involvement. The analysis describes the scripts for the future smart grid interaction investigated in the examined projects, the approaches to user representation, and the project findings concerning consumers and smart grids. Three main dimensions of the scripts are identified and discussed: economic incentives, automation, and information/visualisation. The methods employed for the development of user representations are primarily technical and techno-economic. While our analysis confirms previous findings that economic rationales and automation are central elements of smart grid scripts, the analysis also shows that there is considerable variation in the details of the scripts investigated. Our findings suggest that it may be useful for future smart grid projects to be more systematic and explicit in the analysis of household user perspectives and may consider a broader set of methods in this regard.
Smart grids and households: how are household consumers represented in experimental projects?

Social Life Cycle Assessment: An Introduction

An expansion of the LCA framework has been going on through the development of ‘social life cycle assessment’—S-LCA. The methodology, still in its infancy, has the goal of assessing social impacts related to a product’s life cycle. This chapter introduces S-LCA framework area and the related challenges. It outlines the main conceptual differences between LCA and S-LCA and discusses the barriers in terms of methodological development and potential application. Three case studies are presented applying S-LCA in different contexts and using varying methods. In the light of the outlined differences, perspectives for the future development of S-LCA are discussed.

Measuring the sustainability of goods and services in a systematic and objective manner has become an issue of paramount importance. Life cycle sustainability assessment (LCSA) is a holistic methodology whose aim is to integrate into a compatible format the analysis of the three pillars of sustainability, namely, economy, environment, and society. Social life cycle assessment (S-LCA) is a novel methodology still under development, used to cover the social aspects of sustainability within LCSA. The aim of this article is to provide additional discussion on the practical application of S-LCA by suggesting a new classification and characterization model that builds upon previous methodological developments. The structure of the social analysis has been adapted to maintain coherence with that of standard LCA. The application of this methodology is demonstrated using a case study—the analysis of power generation in a concentrated solar power plant in Spain. The inventory phase was completed by using the indicators proposed by the United Nations Environment Program/Society for Environmental Toxicology and Chemistry (UNEP/SETAC) Guidelines on S-LCA. The impact assessment phase was approached by developing a social performance indicator that builds on performance reference points, an activity variable, and a numeric scale with positive and negative values. The social performance indicator obtained (+0.42 over a range of –2 to +2) shows that the deployment of the solar power plant increases the social welfare of Spain, especially in the impact categories of socioeconomic sustainability and fairness of relationships, whose results were 1.38 and 0.29, respectively.
Socio-technical change: Developing narratives for the Danish energy and transport sector

The choices of more sustainable technologies for citizens are highly dependent on political processes (Kern 2015). To secure impact on actual policy making, stakeholder participation from for instance researchers, policy makers and citizen, is crucial (Volkery and Ribeiro 2009). Although Denmark has the past years done much to increase the amount in of renewable energy in the energy system, the transport sector has not yet been included in the greening process (Sovacool 2013). The transport sector is responsible for almost a quarter of greenhouse emissions in EU, whereof two thirds originate from road transports (EU, 2014). Thus it is important to focus on political actors and processes within socio-technical transitions on this area.

The paper is based on the COMETS project, which main focus is policy advice in the Danish energy and transport sector to achieve a fossil-fuel free energy system in 2050. The data consists of workshops where scientists and stakeholders propose a set of narrative scenarios; a range of interviews; a citizen meeting, where a representative group of the public evaluates the proposed narratives; a future panel in the parliament where the energy groups evaluates scenarios. Different actors can be enrolled into a coalition of change through narratives which include and organise visions and expectations (Smith, Stirling, and Berkhout 2005). Central to this study is the question of how different actors in the Danish energy and transport sector envision possible futures through a scenario planning process. This study investigates the disputes between actors and their conflicting interests in the political arena dedicated to the reproduction of the current regime with an actor-network approach.

In this study we conclude on how different actor groups create and evaluate future scenarios emphasizing the conflicts within the arena among the actor groups.

Solving the pre-marshalling problem to optimality with A* and IDA*

We present a novel solution approach to the container pre-marshalling problem using the A* and IDA* algorithms combined with several novel branching and symmetry breaking rules that significantly increases the number of pre-marshalling instances that can be solved to optimality. A* and IDA* are graph search algorithms that use heuristics combined with a complete graph search to find optimal solutions to problems. The container pre-marshalling problem is a key problem for container terminals seeking to reduce delays of inter-modal container transports. The goal of the container pre-marshalling problem is to find the minimal sequence of container movements to shuffle containers in a set of stacks such that the resulting stacks are arranged according to the time each container must leave the stacks. We evaluate our approach on three well-known datasets of pre-marshalling problem instances, solving over 500 previously unsolved instances to optimality, which is nearly twice as many instances as the current state-of-the-art method solves.

Stakeholder participation in CDM and new climate mitigation mechanisms: China CDM case study

Stakeholder participation is recognized as a key principle for effective climate governance. Climate mechanisms such as the Clean Development Mechanism (CDM), REDD +, and the Green Climate Fund (GCF) provide guidelines for local stakeholder consultation (LSC). However, little empirical research exists on how LSC is practised, and synergies between climate mechanisms are largely unexplored. This study explores how international LSC rules are practised at national and local levels. It aims to better shape future LSC in climate mechanisms by learning from the case of China. First, LSC policies in CDM, REDD +, and GCF are identified. Relevant rules in China's local policies are analysed. To understand the interaction between CDM policies and China's local LSC rules, a selection of Chinese CDM Projects Design Documents (PDDs) are analysed, providing an overall impression of the stakeholder process and results. Afterwards, we focus on a single case for an in-depth understanding of LSC in practice. Results point to the weakness of current CDM LSC rules and lack of good practice guidance, e.g. regarding who to consult, what approaches to be used, and when and how consultations shall take place. It also points to the lack of a clear relationship between global CDM policies and national LSC rules. The weaknesses of existing CDM LSC practices and procedures are not unique to the China case but are relevant to other countries and climate mechanisms. REDD + and GCF provide good examples of LSC rules, where CDM can learn, share experiences, and explore synergies for future revisions.

Stochastic modeling of near-field exposure to parabens in personal care products

Exposure assessment is a key step in determining risks to chemicals in consumer goods, including personal care products (PCPs). Exposure models can be used to estimate exposures to chemicals in the absence of biomonitoring data and as
tools in chemical risk prioritization and screening. We apply a PCP exposure model based on the product intake fraction (PiF), which is defined as the fraction of chemical in a product that is taken in by the exposed population, to estimate chemical intake based on physicochemical properties and PCP usage characteristics. The PiF can be used to estimate route and pathway-specific exposures during both the use and disposal stages of a product. As a case study, we stochastically quantified population level exposures to parabens in PCPs, and compared estimates with biomarker values. We estimated exposure based on the usage of PCPs in the female US population, taking into account population variability, product usage characteristics, paraben occurrence in PCPs and the PiF. Intakes were converted to urine levels and compared with National Health and Nutrition Examination Survey (NHANES) biomonitoring data. Results suggest that for parabens, chemical exposure during product use is substantially larger than environmentally mediated exposure after product disposal. Modeled urine concentrations reflect well the NHANES variation of three orders of magnitude across parabens for the 50th, 75th, 90th, and 95th percentiles and were generally in good agreement with measurements, when taking uncertainty into account. This study presents an approach to estimate multi-pathway exposure to chemicals in PCPs and can be used as a tool within exposure-based screening of chemicals as well in higher tier exposure estimates.

In this paper, we develop a new framework for strategic planning purposes to calculate railway infrastructure occupation and capacity consumption in networks, independent of a timetable. Furthermore, a model implementing the framework is presented. In this model different train sequences are generated and assessed to obtain timetable independence. A stochastic simulation of delays is used to obtain the capacity consumption. The model is tested on a case network where four different infrastructure scenarios are considered. Both infrastructure occupation and capacity consumption results are obtained efficiently with little input. The case illustrates the model's ability to quantify the capacity gain from infrastructure scenario to infrastructure scenario which can be used to increase the number of trains or improve the robustness of the system.
Strategic sourcing and procurement of facilities management services

Purpose: The purpose is to provide insights into strategic sourcing concerning Facilities Management (FM) and how it can contribute to a sourcing decision that combines the benefits of internal and external provision with consideration of business risk and cost.

Design/methodology/approach: The paper investigates a strategic sourcing and procurement process in a large public organisation in Denmark based on participating in internal meetings, a workshop, document studies and interviews. The process is compared to a new ISO standard with guidance on strategic sourcing and development of FM agreements.

Findings: A problem in the new ISO standard is that it is based on sequential model starting with detailing the demand and needs before investigating sourcing option. The case shows that the way needs are specified are depending on the chosen sourcing models. Based on a thorough analysis the organisation decided to change the sourcing strategy with insourcing the most critical building related activities and changing the procurement strategy from one integrated FM contract to 3 bundled and 7 single service contracts. The concept of right-sourcing is discussed.

Research limitations/implications: The research is based on a study of one public organisation, which limits the possibility to generalise the results. However, it provides detailed insights into the strategic sourcing process in FM, which can give inspiration for practitioners and further research.

Originality/value: The paper throws light on a strategic sourcing process which is rarely available in public due to confidentiality considerations and it provides the first evaluation of the new ISO standard from 2016.

Strategic, Tactical and Operational University Timetabling

University education is delivered via lectures and classes that are attended by students. When and where these classes are taught is determined by the timetable. A timetable has many stakeholders, and it is the task of planners to accommodate their needs as far as possible, as it has a significant influence on the daily life of both staff and students. Furthermore, it has a large impact on the use of the university’s resources. Rooms are a significant cost, and as many are allocated specifically to teaching it is important that the planners optimize their use. Creating a high-quality timetable is, therefore, essential to providing an excellent education, while at the same time using the university’s resources efficiently. This thesis presents an introduction to the university course timetabling problem and its different formulations. Although university timetabling has been widely studied in the literature, work has focused on the creation of a schedule once all of the available resources have been determined, called the course assignment problem. This thesis broadens the perspective by also investigating the decision problems that must be solved before and after the course assignment problem. One important problem is to determine the necessary resources. This thesis formulates the room planning problem that determines which rooms are available, and the teaching periods problem that determines timeslots for teaching. It then analyzes how the available resources affect the quality of the timetable. Once the timetable has been generated, there can be disruptions. This thesis investigates the quality recovering problem, which addresses this issue. In this case, an important constraint is that the new solution must be similar to the initial one, but not degrade the quality of the timetable. Solution methods are presented to these four problems. These are based on mixedinteger programming, and the same underlying model is used in different ways to solve decision problems that occur at different levels of the organization. All methods are tested on the curriculum-based course timetabling problem used for the Second International Timetabling Competition, which is the most-studied problem formulation in the literature. Finally, this thesis suggests potential directions for future research, which aims to ensure that there are tangible benefits for planners and universities.

Structured Literature Review of Electricity Consumption Classification Using Smart Meter Data

Smart meters for measuring electricity consumption are fast becoming prevalent in households. The meters measure consumption on a very fine scale, usually on a 15 min basis, and the data give unprecedented granularity of consumption patterns at household level. A multitude of papers have emerged utilizing smart meter data for deepening our knowledge of consumption patterns. This paper applies a modification of Okoli's method for conducting structured literature reviews to generate an overview of research in electricity customer classification using smart meter data. The process assessed 2099 papers before identifying 34 significant papers, and highlights three key points: prominent methods, datasets and
application. Three important findings are outlined. First, only a few papers contemplate future applications of the classification, rendering papers relevant only in a classification setting. Second; the encountered classification methods do not consider correlation or time series analysis when classifying. The identified papers fail to thoroughly analyze the statistical properties of the data, investigations that could potentially improve classification performance. Third, the description of the data utilized is of varying quality, with only 50% acknowledging missing values impact on the final sample size. A data description score for assessing the quality in data description has been developed and applied to all papers reviewed.

**Structuring vendor-client relationships—a combinatorial approach**

Purpose–Vendor-client (VC) relationships play an important role to a company’s general strategy and goals. However, managing these relationships can be a complex undertaking. The purpose of this paper is to assist in identifying the most important factors in assessing a VC relationship and provide a framework leading to a heuristically determined optimal
solution for a company.

Design/methodology/approach – Weighting Factor Comparison (WFC) and scale metrics are used in order to holistically determine a firm’s position regarding relationships with potential vendors. Each contributing factor is analyzed separately using different sub-frameworks, both qualitative and quantitative. Eventually a score is provided, which will be used as input for the holistic framework for the realization of the analysis. Data from a case study of a large multinational company and its relationship with three of its vendors has been used for validation purposes, whereas other factors have been compared to empirical data from literature research.

Findings – The framework presented combines various approaches when handling vendor-client relationships and, therefore, minimizes subjectivity. The factors that have been proven significant for the company’s VC relationship are, in order of significance from higher to lower, Compatibility, Risk, Quality, and Cost.

Practical implications – This study offers a holistic decision making framework for practitioners to continuously determine the most adventitious relationship state between the firm and the various suppliers.

Further research – All frameworks, including the general VC framework, are advised to be implemented to companies.

Originality/value – Although research material is quite extensive regarding various approaches about supplier selection, it is very limited in relation to the evaluation of a vendor-client relationship. Furthermore, when such a relationship is evaluated, only one conceptual framework is chosen, leading to several limitations. This paper combines different frameworks in order to create a holistic framework which incorporates several parameters to determine the value of a vendor-client relationship; thereby exposing potential weaknesses and/or strengths of the relationship.

Studying creativity training programs: A methodological analysis
Throughout decades of creativity research, a range of creativity training programs have been developed, tested, and analyzed. In 2004 Scott and colleagues published a meta-analysis of all creativity training programs to date, and the review presented here sat out to identify and analyze studies published since the seminal 2004 review. Focusing on quantitative studies of creativity training programs for adults, our systematic review resulted in 22 publications. All studies were analyzed, but comparing the reported effectiveness of training across studies proved difficult due to methodological inconsistencies, variations in reporting of results as well as types of measures used. Thus a consensus for future studies is called for to answer the question: Which elements make one creativity training program more effective than another? This is a question of equal relevance to academia and industry, as creativity training is a tool that can contribute to enhancement of organizational creativity and subsequently innovation. However, to answer the question, future studies of creativity training programs need to be carefully designed to contribute to a more transparent landscape. Thus this paper proposes a methodological research standard consisting of three criteria, to which researchers can look when designing future studies of the effectiveness of creativity training.

This review of the literature collects innovative market mechanisms that tend to get overlooked in the discussion of whether unassisted energy-only markets can ensure sufficient capacity or if capacity remuneration mechanisms are required.

The paper complements existing literature reviews and pinpoints advantageous research areas relating to the market design of electricity systems with high shares of variable renewable energy.

Suitability of commercial transport for a shift to electric mobility with Denmark and Germany as use cases

This paper identifies commercial sectors suitable for a shift to electric mobility in Denmark and Germany by analysing daily driving distance. The paper concludes that construction, human health and other service sectors are the most suitable sectors for electric mobility because many vehicles are registered in these sectors and daily mileage is reasonably low. They should be primary target groups of specific policy measures to promote the use of electric vehicles. Both Denmark and Germany have incentives to promote the use of electric vehicles. Nevertheless, electric vehicles do generally not show economic benefits unless travel distance is high. However, today the travel range of large vans is an important barrier for electrification due to battery weight and the limitation of 3.5 tonnes gross vehicle weight for driving with a normal driving licence. The rule needs amendments for electric vehicles, as has been done in Germany. The paper recommends EU countries follow the German rule allowing EVs up to 4.25 tonnes to be driven with a class B licence, thereby potentially creating a market for big vans with long travel range.

Supporting the development of shared understanding in distributed design teams

Distributed teams are an increasingly common feature of engineering design work. One key factor in the success of these teams is the development of short- and longer-term shared understanding. A lack of shared understanding has been recognized as a significant challenge, particularly in the context of globally distributed engineering activities. A major antecedent for shared understanding is question asking and feedback. Building on question-asking theory, this work uses a quasi-experimental study to test the impact of questioningsupport on homogeneous and heterogeneous teams. The results show significant improvement in shared understanding for both team types (27% improvement for heterogeneous and 16% for homogeneous), as well as substantial differences in how this improvement is perceived. This extends theoretical insight on the development of shared understanding and contributes one of few empirical studies directly comparing homogeneous and heterogeneous teams in the engineering design context. This has implications for how distributed teams can be more effectively supported in practice, as well as how shared understanding can be facilitated in engineering design.

Surveying the Environmental Footprint of Urban Food Consumption

Assessments of urban metabolism (UM) are well situated to identify the scale, components, and direction of urban and energy flows in cities and have been instrumental in benchmarking and monitoring the key levers of urban environmental pressure, such as transport, space conditioning, and electricity. Hitherto, urban food consumption has garnered scant attention both in UM accounting (typically lumped with “biomass”) and on the urban policy agenda, despite its relevance to local and global environmental pressures. With future growth expected in urban population and wealth, an accounting of the environmental footprint from urban food demand (“foodprint”) is necessary. This article reviews 43 UM assessments including 100 cities, and a total of 132 foodprints in terms of mass, carbon footprint, and ecological footprint and situates it relative to other significant environmental drivers (transport, energy, and so on) The foodprint was typically the third largest source of mass flows (average is 0.8 tonnes per capita per annum) and carbon footprint (average is 1.9 tonnes carbon dioxide equivalents per capita per annum) in the reviewed cities, whereas it was generally the largest driver of urban ecological footprints (average is 1.2 global hectares per capita per annum), with large deviations based on wealth, culture, and urban form. Meat and dairy are the primary drivers of both global warming and ecological footprint impacts, with little relationship between their consumption and city wealth. The foodprint is primarily linear in form, producing significant organic exhaust from the urban system that has a strong, positive correlation to wealth. Though much of the foodprint is embodied within imported foodstuffs, cities can still implement design and policy interventions, such as improved nutrient recycling and food waste avoidance, to redress the foodprint.

Sustainability assessment of stormwater management systems

We quantify ecotoxicity impacts caused by different solutions to manage stormwater using life cycle assessment. As a novelty, we include emissions of a wide range of pollutants present in runoff. These emissions turn out to be of great importance, especially in decentralized, above surface systems.

Sustainable solar home systems model: Applying lessons from Bangladesh to Myanmar’s rural poor

Myanmar’s rural population has very low access to electricity, mainly due to low disposal income and the remoteness of communities. This paper attempts to test the potential applicability of Grameen Shakti-Infrastructure Development Company Limited (IDCOL), which is a Bangladeshi public private partnership microfinance model, to rural Myanmar towards enhanced solar home systems (SHS) deployment. Rural poor are enabled by this microfinancing scheme to own SHSs in a few years for as low as US$6.40 per month. The objectives of this paper are to assess the experience of Grameen Shakti-IDCOL and other similar projects for invaluable lessons, identify barriers to sustainable electrification for Myanmar’s rural poor and to apply these lessons learned to overcome barriers by developing policy recommendations for sustainable electrification for rural poor in Myanmar. Recommendations are provided suggesting the revision of some assumptions in the National Electrification Plan (NEP) and the creation of a microfinance-based public private partnership, with a polycentric structure, strong local presence and effective after sales service, to increase the deployment of SHSs to sustainably and economically supply modern energy to Myanmar’s rural poor.
Sustainable supply chains in the world of Industry 4.0

Purpose:
Industry 4.0 introduces a series of changes for the supply chain, in particular in terms of technology, structure, connectivity and communication. This presents companies with new opportunities but also new challenges. These emerging trends are affecting the supply chain at a social, economical and environmental level. The sustainable aspect in Industry 4.0 is highly correlated with digitization at a process, product and organizational level (Reichel, 2017). This paper presents a framework for the implementation of Industry 4.0 technologies in new and current business processes while aligning with holistic sustainability goals.

Sustainable Transitions on the Move - Guiding Visions for a Circular Bioeconomy in Scandinavia

Grand societal challenges such as climate change, ageing population and food security feature increasingly on the agenda of policymakers at all scales. While traditional mission-oriented research and innovation policies were largely framed in technical terms, challenge-based policies claim to be less instrumental and more open-ended. One cannot simply specify the problem and develop a diagnosis but one needs to learn about the nature of the grand challenge in order to address it. This implies greater deliberation and contestation, both with respect to policy aims and means, and involves new actor constellations that include a larger variety of actors, and consider new roles for traditional actors (Kuhlmann and Rip 2014). Even if policies start to be aimed at addressing these challenges, this new framing of research and innovation policies is still under-developed and it remains unclear how to implement such policies (Coenen et al. 2015; Schot and Steinmuller 2016).

Systematic Problem Solving in Production: The NAX Approach

This paper outlines the NAX problem solving approach developed by a group of problem solving experts at a large Danish Producer of medical equipment. The company, "Medicimeter" is one of Denmark’s leading companies when it comes to lean and it has developed a strong problem solving culture. The main steps of the approach are to extensively gather direct detailed process knowledge at the actual process, assemble a team that systematically builds on each other ideas, apply team thinking in a structured way to get a rapid and very deep understanding of the problem, and conducting a structured deselection of hypothetical causes to uncover the true root causes. What sets this approach apart from other is that it contains a guide of how to facilitate these steps. A case study was performed in a production department at Medicimeter to demonstrate its effectiveness and reproducibility. It resulted in a close to 60% reduction of the issue concerned.
Although Silicon Nanowire biological Field-Effect Transistors (SiNW-bioFETs) have steadily demonstrated their ability to detect biological markers at ultra-low concentration, they have not yet translated into routine diagnostics applications. One of the challenges inherent to the technology is that it requires an instrumentation capable of recovering ultra-low signal variations from sensors usually designed and operated in a highly-resistive configuration. Often overlooked, the SiNWbioFET/instrument interactions are yet critical factors in determining overall system biodetection performances. Here, we carry out for the first time the system-level sensitivity analysis of a generic SiNW-bioFET model coupled to a custom-design instrument based on the lock-in amplifier. By investigating a large parametric space spanning over both sensor and instrumentation specifications, we demonstrate that systemwide investigations can be instrumental in identifying the design trade-offs that will ensure the lowest Limits-of-Detection. The generic character of our analytical model allows us to elaborate on the most general SiNW-bioFET/instrument interactions and their overall implications on detection performances. Our model can be adapted to better match specific sensor or instrument designs to either ensure that ultra-high sensitivity SiNW-bioFETs are coupled with an appropriately sensitive and noise-rejecting instrumentation, or to best tailor SiNW-bioFET design to the specifications of an existing instrument.

Team cohesion in intensive care nursing: at the interface of nurse self-concept and unit structure

Team cohesion is a critical factor in the provision of high-quality care, yet its antecedents remain understudied, particularly in the context of some healthcare professional groups where structural and individual constraints coexist, and demand for high quality performance is prevailing. In this study, we focus on the nursing group in intensive care units (ICU). Not researched, yet important for employee attitudes towards their workplaces and workgroups, is the interface between the characteristics of individual care providers and those of the teams and organizations in which they are employed. This study examines the effects of three levels of self-concept—individual, relational, and collective—and ICU structural characteristics such as size (number of nurses), nurse training profile, and number of beds. These factors are investigated as they jointly shape the degree to which nurses perceive their teams as cohesive. A multi-source and multi-level study of approximately 140 nurses employed in 20 ICUs across Denmark demonstrates the critical role of self-concept in easing and enhancing the constraints workplaces impose on team cohesion. Furthermore, the study confirms the positive relationship between overall team member-rated cohesion and manager-rated quality of care. Hence, understanding the interplay among self-concept, ICU structural characteristics, and team cohesion is highly relevant to enhancing quality of care.

Technological Innovation and Beyond: Exploring Public Value of University Inventions Based on Contingent Effectiveness Model

University inventions are traditionally seen as significant input into development of new technologies and innovations in the market as they generate growth and regional development. (REF) Yet, these inventions developed into new technologies can simultaneously create public values such as those that are related with sustainability goals. In this paper, we apply the Contingent Effectiveness Model by Bozeman et.al. (2015) as a framework to consider the effectiveness of technology transfer from university to industry via licensing, and examine what values derive during the commercialization process of university inventions. We define four main values: technological, economic, social and environmental, and place the latter two under the concept of public value. The aim of this paper is to expand the understanding of public value and incorporate it into technology transfer literature. We assign to the concept of public value a measurement tool, thus, making public value a measurable concept. Therefore, this study not only extends conceptual and theoretical considerations of public value (Jørgensen and Bozeman 2007), but it also provides evidence based on collected data. A unique data set from survey of university licensee companies reveals that university inventions that are accomplished technologically, often create added public value, social or environmental, or both.

General information
Testing the slope model of scheduling preferences on stated preference data

The valuation of travel time variability is derived either from a structural model, given information on departure time, or directly from a reduced-form model where departure time is assumed to be optimally chosen. The two models are theoretically equivalent under certain assumptions, hence are expected to yield similar results. We use stated preference data to compare the valuation of travel time variability under a structural model where trip-timing preferences are defined in terms of time-dependent utility rates, the "slope model", against its reduced-form model. Two choice experiments are used that are identical except one has a fixed departure time while the other allows respondents to choose departure time freely. The empirical results in this paper do not support the theoretical equivalence of the two models as the implied value of travel time variability under the reduced-form model is an order of magnitude larger. This finding, which is robust to various specification tests, is in line with a recent Swedish study by Börjesson, Eliasson and Franklin [Transportation Research Part B: Methodological, 46(7), 855-873 (2012)]. Since our data allows a direct comparison of the two approaches, we are able to rule out some potential explanations lined up by past research for the observed discrepancy between the two models.
The absolute environmental performance of buildings

Our paper presents a novel approach for absolute sustainability assessment of a building's environmental performance. It is demonstrated how the absolute sustainable share of the earth carrying capacity of a specific building type can be estimated using carrying capacity based normalization factors. A building is considered absolute sustainable if its annual environmental burden is less than its share of the earth environmental carrying capacity. Two case buildings – a standard house and an upcycled single-family house located in Denmark – were assessed according to this approach and both were found to exceed the target values of three (almost four) of the eleven impact categories included in the study. The worst-case excess was for the case building, representing prevalent Danish building practices, which utilized 1563% of the Climate Change carrying capacity. Four paths to reach absolute sustainability for the standard house were proposed focusing on three measures: minimizing environmental impacts from building construction, minimizing impacts from energy consumption during use phase, and reducing the living area per person. In an intermediate path, absolute sustainability can be obtained by reducing the impacts from construction by 89%, use phase energy consumption by 80%, and the living area by 60%.

The Attentional Capture of Colour in Visual Interface Design: A Controlled Environment Study

The use of colour is an integral component in visual interface design for creating separation between objects and for conveying meaning. It has previously been established that colours can be separated in a hierarchy of primary colours and secondary colours, and that colours are consistently associated with specific mood tones. However, it has thus far not been investigated whether these two factors, which we refer to as the perception-primacy and emotion-conveyance, are associated with attentional capture in a congruent manner. To investigate this, we conducted a visual search task study in
a controlled environment, in which 11 participants scanned a 20 item display for a coloured target amongst coloured
distractors. We found evidence to support that primary colours capture attention significantly more than secondary colours,
and inconclusive evidence that colours convey their meaning at a sufficiently early level of processing to influence
attention. We end by discussing implications of our results for design practice and research in psychology.

The Challenges of Applying Planetary Boundaries as a Basis for Strategic Decision-Making in Companies with Global
Supply Chains
The Planetary Boundaries (PB) framework represents a significant advance in specifying the ecological constraints on
human development. However, to enable decision-makers in business and public policy to respect these constraints in
strategic planning, the PB framework needs to be developed to generate practical tools. With this objective in mind, we
analyse the recent literature and highlight three major scientific and technical challenges in operationalizing the PB
approach in decision-making: first, identification of thresholds or boundaries with associated metrics for different
geographical scales; second, the need to frame approaches to allocate fair shares in the 'safe operating space' bounded
by the PBs across the value chain and; third, the need for international bodies to co-ordinate the implementation of the
measures needed to respect the Planetary Boundaries. For the first two of these challenges, we consider how they might
be addressed for four PBs: climate change, freshwater use, biosphere integrity and chemical pollution and other novel
entities. Four key opportunities are identified: (1) development of a common system of metrics that can be applied
consistently at and across different scales; (2) setting 'distance from boundary' measures that can be applied at different
scales; (3) development of global, preferably open-source, databases and models; and (4) advancing understanding of the
interactions between the different PBs. Addressing the scientific and technical challenges in operationalizing the planetary
boundaries needs be complemented with progress in addressing the equity and ethical issues in allocating the safe
operating space between companies and sectors.

The characteristics to consider in municipal shared spaces

Purpose
The purpose of this study is through collaboration with practitioners to identify key characteristics of municipal shared spaces and, based on these, developing a guide for establishing a shared space in a municipal real-estate portfolio.

Design/methodology/approach
This paper builds on existing theory on the subject of shared space as well as the practical experience of professionals within the fields of property management, space management and facilities management. The guide presented is the result of data collected through case studies, interviews, surveys and literature reviews. This knowledge is combined with data collected through a workshop with practitioners from municipalities and the private sector, to provide a final guide that is directly applicable as a tool for working with shared space as a part of a property management strategy.

Findings
The result presented is a guide to establishing a shared space in a municipal real-estate portfolio, created in collaboration between researchers and practitioners. It provides an introduction to the topic and outlines a number of tasks that must be completed in different parts of a project, thereby providing a tool which practitioners can use to realise shared space as a strategy in the context of public real-estate management.

Originality/value
The guide presented is a first in connecting theory with practical application and through collaboration between researchers and practitioners, creating a tool to be used when working with shared space in a municipal real-estate portfolio.
The Circular Economy: In Practice-focused Undergraduate Engineering Education

The growth of the planet’s population makes the traditional industrial model of “take, make and waste” unsustainable. The circular economy, in which resources are continuously reused, offers a solution. For manufacturers of durable goods the circular economy requires a well-functioning circular supply chain that includes reverse logistics, product recovery operations, development of markets for recovered products, and integration of reuse and product recovery into the firm’s daily operations. How to educate undergraduate practice-focused engineers in the design, implementation, and operation of circular supply chains is un-explored and the purpose of the paper is to identify a suitable teaching method. Because courses in circular supply chain topics are currently non existent, the paper first develops a set of learning goals based on the skillset necessary to design, implement, and operate a circular supply chain. Second, the paper examines whether the teaching method of a similar cross-disciplinary course in innovation can be successfully applied. This teaching method is based on cross-disciplinary team projects that work with innovation in cooperation with a participating firm. The study concludes that the teaching method can be (largely) applied. However, future research should test the paper’s results with studies using data from circular supply chain courses.

The documentation of product configuration systems: A framework and an IT solution
When designing and maintaining a product configuration system (PCS), complete and up-to-date documentation of the system is needed in the form of a product model that outlines the structures, attributes, and constraints of the PCS. Furthermore, up-to-date documentation for the PCS is crucial for maintenance, further development, system quality and communication with domain experts. Product models are the main communication and documentation tools used in PCS projects. Recent studies have shown that up-to-date documentation for the PCS is often lacking due to the significant amount of work required to maintain product models. To address these challenges, this paper proposes an approach for documenting the PCS that is based on the structure, attributes, and constraints modelled within the PCS, in which the product model is generated directly from the PCS. The suggested approach avoids knowledge duplication, as knowledge needs to be maintained within the PCS only. It involves two steps: the first is the building of the initial product model, which
is used for the programming of the PCS. In the second step, the product model is generated directly from the PCS and is based on the structure, attributes, and constraints inside the PCS. The product model does not need to be maintained, therefore, outside the PCS. This approach meets the demand for agile documentation and efficient communication with domain experts, and uses the fewest resources possible. Furthermore, to support the framework, an IT documentation system is proposed that is capable of retrieving knowledge from the PCS and thus generating the product model. Our framework and IT documentation system were developed and tested at a case company on five different projects. The results confirm that benefits can be achieved by using the proposed IT documentation system, as time and resources are saved, while the quality of the PCS is improved.

The Effect of Path-Dependence and Uncertainty on the Value of Mature Technologies

This paper examines whether technological advances benefit more from path-dependent or path-creating capabilities. Consistently with recent advances in the literature, we argue that multiple technological trajectories can coexist in a field; therefore, firms may contribute to technological development by recombining in novel ways the capabilities that are widespread in the field, or by building novel and rare capabilities. The paper also conceptualises how technological uncertainty affects the value of such capabilities. Using patent data from 1977 to 2007 for firms developing the hydrocracking technology, the paper finds that both rare and widespread capabilities are valuable to the invention process, thereby suggesting that both path-dependent and path-creating strategies are beneficial for technological development. The paper shows that uncertainty has an inverted U-shaped effect on invention value. In particular, under conditions of low uncertainty, path-dependent capabilities tend to be more valuable.

The evolution of green food products and retailers' eco-strategizing and green competitiveness in the Danish and Brazilian grocery sector

Grounded on the evolutionary approach, this thesis adds an understanding about the dynamics of the greening of the economy, particularly highlighting the neglected demand side aspect of the greening of markets. Since the emergence of green food markets in the 1980s and 1990s, this study investigates the role of retail groups in the development of the green food market in Denmark and Brazil. Accordingly, it investigates the rate and direction of the greening of this process in those markets as well as their sectoral convergence of retailers' eco-strategizing. Using the dynamic capabilities framework, it examines why, how and when the eco-strategizing, green performance and competitiveness of grocery retail groups co-evolved with the development of the green food market in Denmark and Brazil. This thesis contributes innovatively to research on at least three more aspects. Firstly, it advances the existing literature in adding combined qualitative and quantitative longitudinal firm-level data, which is analysed over time through a framework composed by macro, meso and micro indicators of the green market development. Secondly, it provides the perspectives of the surveyed retail groups and market support stakeholders acting in the Danish and Brazilian green food markets. Thirdly, it provides estimation of the green food turnover in the Brazilian retail. This thesis concludes that major retail groups in Denmark and Brazil were not the pioneers in the green food market. Nonetheless, these large retailers in collaboration with local organic food producers and market support stakeholders were rather central in making the green food market a viable business case. These retail groups were key players in the evolution of the green food market as they have played a vital role in scaling up the Danish and Brazilian green food markets to higher turnover levels at least since the 1990s. Furthermore, these retail firms sensed the market potential for the green food products in the 1980s and 1990s and particularly in the 2000s and onwards, and through emergently deliberate eco-strategizing have been able to size and transform the green food market in Brazil and Denmark. These retailers' eco-strategizing implied innovative changes in their business models, which have become markedly greener in this period due to their role in the development of the Danish and Brazilian green food markets and hence the rise of a green business case. Finally, changes in their business models have become a central competitive driver to retailers in both countries, which enabled them to sustain competitive advantage on the greening of their food markets.
The Evolution of South-South Development Cooperation: Guiding Principles and Approaches

South-South Cooperation (SSC) has attracted the attention of the development community in terms of both its 'impact' on traditional aid and the integration of its values into the work of multilateral institutions, making it the new 'buzzword' of the aid community. However, few studies have been carried out to understand the rationale of SSC and how it influences the approaches followed in its development assistance activities or 'South-South Development Cooperation' (SSDC). Therefore, this article explores the origins and development of the SSC concept from the perspectives of southern countries and shows how they affect the narrative related to the implementation model of SSDC. The research uses a narrative literature review focusing on southern countries' understandings of both SSC and SSDC, thus enabling two sets of categorization: one for the conceptual elements in the definition of SSC outside its geographical component and the other for the guiding principles and approaches of SSDC.

The Fear of Pain Questionnaire-III and the Fear of Pain Questionnaire-Short Form: a confirmatory factor analysis

Background: The Fear of Pain Questionnaire-III (FPQ-III) is a widely used instrument to assess the fear of pain (FOP) in clinical and nonclinical samples. The FPQ-III has 30 items and is divided into three subscales: Severe Pain, Minor Pain and Medical Pain. Due to findings of poor fit of the original three-factor FPQ-III model, the Fear of Pain Questionnaire-Short Form (FPQ-SF) four-factor model has been suggested as an alternative. The FPQ-SF is a revised version of the FPQ-III, reduced to 20 items and subdivided into four subscales: Severe Pain, Minor Pain, Injection Pain and Dental Pain.

Aims and methods: The purpose of the study was to investigate the model fit, reliability and validity of the FPQ-III and the FPQ-SF in a Norwegian nonclinical sample, using confirmatory factor analysis (CFA). The second aim was to explore the model fit of the two scales in male and female subgroups separately, since previous studies have uncovered differences in how well the questionnaires measure FOP across sex; thus, the questionnaires might not be sex neutral. It has been argued that the FPQ-SF model is better because of the higher fit to the data across sex. To explore model fit across sex within the questionnaires, the model fit, validity and reliability were compared across sex using CFA.

Results: The results revealed that both models' original factor structures had poor fit. However, the FPQ-SF had a better fit overall, compared to the FPQ-III. The model fit of the two models differed across sex, with better fit for males on the FPQ-III and for females on the FPQ-SF.

Conclusion: The FPQ-SF is a better questionnaire than the FPQ-III for measurement of FOP in Norwegian samples and across sex subgroups. However, the FPQ-III is a better questionnaire for males than for females, whereas the FPQ-SF is a better questionnaire for females than for males. The findings are discussed and directions for future investigations outlined.

The Financial Crisis and Diverging House Prices: Evidence from the Copenhagen Metropolitan Area: 2017-084/VIII

This paper investigates the development of house prices in Copenhagen in the period 1994-2013, while paying special attention to the heterogeneous impact of the boom and bust periods along the dimensions of housing type (single vs multifamily housing), geography and quality. To allow for price developments that can differ by quality, we use a recently developed generalization of the conventional Muth model that assumes a constant unit price across the quality spectrum. It allows us to separately consider the development of house prices and quality in Copenhagen neighbourhoods. Moreover, we investigate the validity of the common assumption of a constant unit price and reject it decisively. We use detailed housing transaction data for the greater Copenhagen area. We show that the housing boom of the 2000’s and the bust that followed hit the lowest quality segments significantly harder than the high quality segments of the housing market.

The Global Goals for Sustainable Development in Engineering Education

History is full of examples of how engineers for good and bad have invented and implemented technologies, with consequence far beyond their imaginations. Think for instance on the development of the combustion engine which enabled a revolution in transport and individual mobility but at the same time contributed to CO2 emissions and thus global warming. Or digital technologies that through the internet and social media have created platforms for information sharing and identity building in a globalized world but at same time creates more polarized and post factual societies. A recent study by across 11 countries conducted among 10,341 respondents finds that engineering indeed played a vital role in creating our past and will continue to play a critical role in shaping our future. While this finding mirrors the common understanding of engineering, the study points to a need to change the role of engineering from "inspire new innovations" to "solving the world’s problems". (QEPrize 2015) United Nations recently conceptualized crucial world’s problems in the form of Sustainable Development Goals (SDGs) as illustrated in the following figure. The SDGs are a universal call to action to end poverty, protect the planet and ensure that all people enjoy peace and prosperity. (United Nations 2015). Today the goals are adopted by all 193 UN member states and explicitly addressed by more than 9,000 companies in 170 countries representing nearly every sector and size (Global Compact 2017). Despite its current widespread diffusion, continues support for the SDGs through science and education is of utmost importance in the actual realization of the goals by 2030 (UN-SG-SAB 2014). This workshop targets the role of engineers as persons who solve societal challenges. It will facilitate a discussion and will share some approaches to address the following question: “How could we embed SDGs in engineering education?” We do this through a workshop facilitated as a knowledge café where the participants collectively explore how could we embed SDGs in engineering education, through several educational practices across the learning journey of engineers. A ‘Knowledge Café’ “aims to provide an open and creative conversation on a topic of mutual interest to surface their collective knowledge, share ideas and insights, and gain a deeper understanding of the subject and the issues involved.” (Wikipedia). Participants of a ‘Knowledge Café’ rotate in small groups across different ‘stations’, in each station the group will discuss a different aspect of the problem, in our case, how to embed SDGs in engineering education. Specifically we will explore practices to connect the SDGs to core educational activities: courses, extra curriculum projects, individual major pieces of work like master and bachelor thesis, the overall learning environment of the university. Following the collective discussion and wrap of the workshop, the authors present their experiences working with SDGs in teaching project management to engineering students. Our findings from educating more than 500+ students is that the SDGs represent an outstanding tool to convey the importance of engineering and to create a sense of purpose that represent a key driver for motivation. It further it enables collaboration between various disciplines and stimulates personal reflections on "what legacy do I want to leave?” and “what projects should I engage in?”
The HERA Approach To Morally Competent Robots

To address the requirement for autonomous moral decision making, we introduce a software library for modeling hybrid ethical reasoning agents (short: HERA). The goal of the HERA project is to provide theoretically well-founded and practically usable logic-based machine ethics tools for implementation in robots. The novelty is that HERA implements multiple ethical principles like utilitarianism, the principle of double effect, and a Pareto-inspired principle. These principles can be used to automatically assess moral situations represented in a format we call causal agency models. We discuss how to model moral situations using our approach, and how it can cope with uncertainty about moral values. Finally, we briefly outline the architecture of our robot IMMANUEL, which implements HERA and is able to explain ethical decisions to humans.

The Hybrid Ethical Reasoning Agent IMMANUEL

We introduce a novel software library that supports the implementation of hybrid ethical reasoning agents (HERA). The objective is to make moral principles available to robot programming. At its current stage, HERA can assess the moral permissibility of actions using the principle of double effect, and it can make utilitarian judgments. We present the prototype robot IMMANUEL based on HERA. The robot will be used to conduct research on joint moral reasoning in human-robot interaction.
The impact of CO2-costs on biogas usage

The Danish government has set a target of being fossil fuel independent by 2050 implying that a high degree of inflexible renewable energy will be included in the energy system; biogas can add flexibility and potentially has a negative CO2-emission. In this paper, we investigate the socioeconomic system costs of reaching a Danish biogas target of 3.8 PJ in the energy system, and how CO2 costs affect the system costs and biogas usage. We perform our analysis using the energy systems model, Balmorel, and expand the model with a common target for raw biogas and upgraded biogas (biomethane). Raw biogas can be used directly in heat and power production, while biomethane has the same properties as natural gas. Balmorel is altered such that natural gas and biomethane can be used in the same technologies. Several CO2-cost estimates are investigated; hereunder a high estimate for the expected CO2-externality costs. We find that system costs increase with CO2-costs in most cases, while the biogas target becomes socio-economically cheaper. In the case of a very high CO2-cost, system costs decrease and biomethane becomes the primary fuel. Furthermore, biomethane functions as regulating power and the Danish fuel consumption increases due to a higher electricity export.
The implications of the new sulphur limits on the European Ro-Ro sector

In an effort to reduce the environmental impacts of maritime transportation, the International Maritime Organization (IMO) designated special Sulphur Emission Control Areas (SECAs) where ships are required to use low-sulphur fuel. In January 2015, the sulphur limit within SECAs was lowered to 0.1%, which can only be achieved if vessels are using pricier ultra-low sulphur fuel, or invest in abatement technologies. The increased operating costs borne by Ro-Ro operators in SECAs due to the stricter limits can result in the shutting down of some routes and a redistribution of cargo flows with land-based alternatives. The exact repercussions of the new sulphur limits are difficult to identify in the wake of significant recent reductions of the fuel prices for both low-sulphur and heavy fuel oil. This paper presents a modal split model that estimates modal shifts vis-a-vis competing maritime and land-based modes available to shippers. This allows examining the implications of the recent low prices to modal choice, and the influence a potential increase in fuel prices may have. The model is applied to seven routes affected by the regulation based on data from a leading European Ro-Ro operator. Sensitivity analyses on market share data, cargo values, freight rates, and haulers rates are conducted. Emissions inventories are constructed to assess the environmental efficacy of the SECA regulation. The novelty of the proposed model lies in the examination of the ex-post implications of shutting down a service and the redistribution of transport. Recommendations to mitigate and reverse the negative side-effects of such environmental legislation are proposed.

Robert Batterman claims that asymptotic explanations in physics are acausal, involve un-deidealizable idealizations and are counter-examples to the mapping account of the role of mathematics in physics. In this paper, I analyze and criticize aspects of this claim, especially its implications for metaphysics and to a lesser extent methodology in physics. Regarding causality, Batterman has advocated that explaining emergent physical phenomena such as the universality of critical exponents in phase transitions involve throwing away causal details, and that we should replace Kim's requirement of emergents having novel causal powers with emergents figuring in novel explanatory stories, see (Batterman, 2002). I argue that Batterman's view of causality is ontologically too restrictive. I also argue that it is methodologically too
restrictive, in that abstractions in science, including some involved in examples given by Batterman, e.g. (Batterman, 2002) (Batterman, 2009) almost always involve throwing away details (causal or otherwise), but that this does not imply throwing away the category itself (e.g. causality), see also (Batterman & Rice, 2014), (Lange, 2015). I further argue that even if physical explanations do not directly appeal to causal factors at the macro level, they presuppose them. For instance, the modeler’s choice of which parameters (or dimensions) are essential to the explanation of a certain phenomenon and which are consequently taken as a starting point for a dimensional analysis, see (Batterman, 2002), (Barenblatt, 1979), presupposes a causal structure of the universe in terms of dependent and independent variables. Sometimes such presuppositions can be explicited as ontological assumptions built into systems of units of measurement. If no causality is presupposed, the account 2 will be subject to the same type of criticism as the deductive-nomological model, e.g. why not explain the length of strings of pendulums via an analysis of parameters connected to their periods and gravitational acceleration? I conclude that although asymptotic explanations do not directly appeal to causality, they do not exclude causality at the macro-level and there are many prima facie reasons to keep causality at this level. I defend this against claims made about the existence of noncausal explanations in physics, e.g. by claiming that physical explanations require a global theory, see (Wayne, 2015) or that they proceed by appealing to fictional highly idealized models in physics, see (Bokulich, 2011), (Pexton, 2014), (Wayne, 2015). I claim that these arguments do not preclude that causality is presupposed at the macro-level, except perhaps in quantum theoretical explanations in which case an appeal to Bohr’s correspondence principle may be required, a mystery which will not be solved here. Going into more details with asymptotic explanations, I argue that Batterman’s argument that these are mathematical operations and not mathematical structures, see (Batterman, 2010), is not convincing, as the distinction between a mathematical operation and a structure is very hard to uphold. I also argue that his argument that they are counterexamples to the mapping account of mathematical explanations in physics is imprecise in one aspect, as an idealized misrepresentation of a phenomenon is still a representation of that phenomenon. I find at the core of Batterman’s view on asymptotic explanations an ineliminable distortion of reality, the appeal to the singularity. One central problem in that discussion is whether we should consider reality itself as distorted in the singularity, and our representation of it to be correct in some sense, or we should say that our representation of reality is distorted and important aspects of reality are unknown to us? I comment on this question. I conclude that the existence of asymptotic explanations should not influence our views of causality at the macro-level and that they are not convincing counter-examples to the mapping account of 3 mathematical explanation in physics. They do, however, point to a very central problem in the interpretation of physical terms, i.e. what actually happens in the singular limit?

The influence of fertiliser and pesticide emissions model on life cycle assessment of agricultural products: The case of Danish and Italian barley
Barley is an ancient crop and a great source of nutrients. It is the third largest agricultural commodity produced in Denmark and represents a relevant crop in Italy too. Due to the increasing customers awareness of sustainability issues, it has become essential to evaluate the environmental impact and the use of resources in food production and distribution systems. However, especially in agriculture, difficulties are encountered when emissions from fertilisers and pesticides need to be modelled, due to a variety of modelling options and their dependency on the availability of site-specific information. How to address these difficulties might affect the results reliability. Hence, this study aims to evaluate, using the life cycle assessment (LCA) methodology, the influence of different models for estimating emissions from fertilisers and pesticides on the environmental impacts of barley cultivation in Denmark and Italy. Two models for fertilisers and pesticides’ emissions have been applied; these differ on the extent of data requirements and complexity of calculation algorithms, which might increase the results accuracy and robustness. The results show that the modelling options do affect the environmental impacts of barley production, in particular climate change, eutrophication categories, acidification and freshwater eco-toxicity. This study estimates that the variations for such categories range from 15% in the case of climate change to 89% in the case of marine eutrophication. These findings highlight the importance of the emission modelling options as well as the constraints of data requirements, critical aspects when a LCA study on agricultural products is carried out.

The Key to Successful Operational Due Diligence: The right data, at the right time, analysed in the right way

Purpose:
The purpose of this paper is to describe both qualitative and quantitative operational determinants influencing the acquisition decision in the due diligence phase of a Merger & acquisition (M&A). The operational due diligence (ODD) process is largely unexplored in extant literature and only fragmented and unexhaustive literature exist. This research focuses on developing a dynamic end-to-end framework for conducting an ODD. The framework is structured around each area of the supply chain and help practitioners obtain key insights in the acquisition target, based on a range of key questions, data points and analyses.

Methodology:
Due to the complex nature of the research objective, a qualitative approach is used to provide rich and in-depth data. The explorative approach of the study allows for thorough understanding of the research area. Therefore, the case-study approach is the most appropriate research methodology (Yin, 1989; Oakley, 1999). In-depth data from multiple cases were selected and analyzed based on interviews – and in some cases workshops - with private equity professionals (acquirer) and private equity advisors. To ensure a sufficient empirical foundation, an online survey will also be developed. The research is divided into five key phases (i) an extensive literature review of research papers and industry publications; (ii) survey design and analysis of the responses (iii) semi-structured interviews, and workshops in the case companies; (iv) structured comparison of the literature review and the empirical data; and (v) development of a novel and dynamic framework that assists the performing acquires and advisors that conducts operational due diligence.

Findings:
A first important finding from the literature review is the research gap concerning operational due diligence. In addition, a structured normative framework is lacking. Collectively the literature review and the empirical studies revealed following operational due diligence determinants assessed across all supply chain components (Recardo 2014):

- **People & Organization** – Capabilities and competencies, corporate culture, organizational structure and personnel infrastructure.
- **Facilities** - Factory, machinery, human resources, capex requirements.
- **IT & System** – Data, Systems, Tools and documentation
- **Operating Cost & Capital** – Cost and capital structure: fixed costs, variable costs and asset.
- **Scalability & Risk** – Capabilities, technologies and external environment.
- **Improvement Potentials** – Rationalization and Efficiency.
- **Synergies** - Facility consolidation, Overhead reduction, purchasing power, other redundancies.

Each of these areas is supported by a range of underlying data points that are utilised to conduct a sufficient analyses leading to key insights for the acquirer.

Value:
The paper contributes with empirical research within M&As and specifically ODD, which has not been well-researched. In addition, the paper provides results which can be useful for both due diligence practitioners and researchers by (i) identifying operational determinants influencing the acquisition decision in the due diligence phase, and (ii) structuring a practical end-to-end framework which incorporates all supply chain elements, ensuring a comprehensive ODD.

Practical implications:
The research is focused around industrial applicability and the proposed framework can serve as support to practitioners who perform ODD.
The Limits of Logic-Based Inherent Safety of Social Robots

Social robots can reason and act while taking into account social and cultural structures, for instance by complying with social or ethical norms or values. As social robots are likely to become more common and advanced and thus likely to interact with human beings in increasingly complex situations, ensuring safety in such situations will become very important. In this chapter, I investigate the safety of social robots, focusing on the idea that robots should be logically guaranteed to act in a certain way, here called logic-based inherent safety. A meta-logical limitation of a particular program for logic-based safety for ethical robots is shown. Afterwards, an empirical study is used to show that there is a clash between deontic reasoning and most formal deontic logics. I give an example as to how this clash can cause problems in human-robot interaction. I conclude that deontic logics closer to natural language reasoning are needed and that logic only should play a limited part in the overall safety architecture of a social robot, which should also be based on other principles of safe design.

The liquefied natural gas infrastructure and tanker fleet sizing problem

We consider a strategic infrastructure and tanker fleet sizing problem in the liquefied natural gas business. The goal is to minimize long-term on-shore infrastructure and tanker investment cost combined with interrelated expected cost for operating the tanker fleet. A non-linear arc-based model and an exact solution method based on a set-partitioning formulation are developed. The latter approach allows very fast solution times. Computational results for a case study with a liner shipping company are presented, including an extensive sensitivity analysis to account for limited predictability of key parameter values, to analyze the solutions' robustness and to derive basic decision rules.

The Meaning of System: Towards a Complexity Orientation in Systems Thinking

This article reviews the generic meaning of ‘system’ and complements more conventional system notions with a system perception based on recent complexity theory. With system as the core concept of systems theory, its actual meaning is not just of theoretical interest but is highly relevant also for systems practice. It is argued that complexity theory and thinking with reference to Luhmann a.o. ought to be recognised and paid attention to by the systems community. Overall, it is found that a complexity orientation may contribute to extend and enrich the explanatory power of current systems theory when used to complex real-world problems. As regards systems practice it is found that selective use and combination of five presented research approaches (functionalist, interpretive, emancipatory, postmodern and complexity) which function as different but complementing ‘epistemic lenses’ in a process described as constructive circularity, may strengthen the exploration and learning efforts in systems-based intervention.

The multi-port berth allocation problem with speed optimization and emission considerations

The container shipping industry faces many interrelated challenges and opportunities, as its role in the global trading system has become increasingly important over the last decades. On the one side, collaboration between port terminals and shipping liners can lead to costs savings and help achieve a sustainable supply chain, and on the other side, the optimization of operations and sailing times leads to reductions in bunker consumption and, thus, to fuel cost and air emissions reductions. To that effect, there is an increasing need to address the integration opportunities and environmental issues related to container shipping through optimization. This paper focuses on the well known Berth Allocation Problem (BAP), an optimization problem assigning berthing times and positions to vessels in container terminals. We introduce a novel mathematical formulation that extends the classical BAP to cover multiple ports in a shipping network under the assumption of strong cooperation between shipping lines and terminals. Speed is optimized on all sailing legs between ports, demonstrating the effect of speed optimization in reducing the total time of the operation, as well as total fuel consumption and emissions. Furthermore, the model implementation shows that an accurate speed discretization can result in far better economic and environmental results.

The Nordic model*: historical origins and its significance for the workplace dialogue towards increased organizational sustainability

The vision of the NOVO network is “a Nordic Model for development of more sustainable production systems in healthcare”. It is based on the assumption that the Nordic countries, through high levels of trust and justice (social capital), have unique opportunities to carry out dialogue-based change processes, cf. “the Nordic Model”. This seems important due to the frequent negative impact of rationalization on ergonomics and vice versa (see previous abstract by Winkel et al). The Nordic model has been the subject of extensive discussions and studies (e.g. Schiller et al., 1993). The Nordic exceptionalism might first be noticeable in the Middle Ages in the weak feudalism compared to the Continent. The peasants of the North were personally free and owned their land. They paid taxes and were the direct subjects of the Crown. Correspondingly, the nobility was weak. At the time of the industrial breakthrough in the 19th century, industrial workers were recruited from the landless, often sons and daughters of self-owning farmers. Before the advent of the labour movement, dialogue instead of violence was the trusted way for the popular movements to advance their cause. The international revolutionary orientation of the trade unions was already during the 1890s subordinated to negotiations with national employers. The collective agreement is the counterpart to the share contract (in Danish: “Andelskontrakt”), which created and structured social capital in the agricultural development in Denmark. The collective agreement also begun its successful spread in Denmark and became dominant in the whole of the North. The class conflicts took place in countries without major ethnic, cultural and religious splits. In a European comparison class differences were relative moderate. The state had a limited record of active repression and corruption. To-day we still have the best organized trade unions in the world, close cooperation with important social democratic parties, strong employer organizations, early recognition of trade unions and established policy of collective bargaining with close to total coverage of the labour market and a principle of no-state intervention in industrial conflicts. Thus, the industrial relations in the Nordic countries still seem to be exceptional. Key research issues are now to further investigate the Nordic Model in terms of:

- critical prerequisites for a positive environment for dialogues based on workplace agreements
- how such insights can be measured and further developed
- how they can be made available to a wider audience in an applicable way

The NOVO Network: the original scientific basis for its establishment and our R&D vision
The NOVO network is a Nordic non-governmental professional association whose aims are to foster the scientific progress, knowledge and development of the working environment within Healthcare as an integrated part of production system development. The vision is a “Nordic Model for Sustainable Systems” in the healthcare sector. It was founded in
2006 in Copenhagen and was financially supported by the Nordic Council of Ministers from 2007 to 2015. The motivation to establish the NOVO Network arose when reviewing the literature regarding opportunities to create sustainable production systems. This work was initiated year 2002 and resulted in a systematic review published 2011 (Westgaard and Winkel 2011). Already in 2006 it was concluded that ergonomic interventions have limited musculoskeletal and mental health effects in a long-range perspective while rationalization has predominant negative health effects – particularly within healthcare. This was the basis for creating the NOVO triangle emphasizing that intervention research for improved work environment in healthcare also needs to consider efficiency and quality aspects to increase organizational sustainability; i.e. the joint consideration of competitive performance and working conditions in a long term perspective. Interventions aiming at increasing organizational sustainability thus demand new forms of collaboration and coordination between workers, management, designers, and ergonomicists. Such collaborations will often be challenged due to the frequent negative impact of rationalization on ergonomics and vice versa. This call for dialogue processes between the stakeholders taking more holistic systems perspectives. Dialogue-based change processes may be more common in the Nordic countries compared to other parts of the world. It is argued that the Nordic countries have unique opportunities in this respect (see the following abstract by Schiller et al), with a potential successful outcome in terms of macroeconomic indicators (discussed by Olesen et al., 2008). Thus, we suggest increased focus on our vision: “a Nordic Model for development of more sustainable production systems in healthcare”. Future R&D performed within the framework of our NOVO network should substantiate this hypothesis. In practical terms, this necessitates expanded research protocols.

The rationality of intuition: Studying adaptive heuristics in project decision-making

This paper presents a research agenda for studying adaptive heuristics in project decision making. Project decisions are a potentially fruitful research field for adaptive heuristics. These decisions typically take place under time and information constraints, with high complexity and ambiguity - environments in which adaptive heuristics typically strive as effective decision tools. Yet, project decisions as a research topic introduce challenges that are currently not considered in the main body of adaptive heuristics research: the issue of group decision making, and the element of an unpredictable future that is shaped by the project as it is carried out. The proposed research agenda highlights potential research problems within a descriptive and a prescriptive stream of the research. Furthermore, the article presents conventional methodologies to study adaptive heuristics, discusses the limitations of these methods for project decision-making, and suggests alternative methodologies, suitable to cope with group decision-making and irreducible uncertainty.

The real governance of disaster risk management in peri-urban Senegal: Delivering flood response services through co-production

Disastrous and recurring floods have impacted West African urban centres over the last decade, accentuating already existing vulnerabilities in poor neighbourhoods. Climate change-induced changing weather patterns and more extreme weather events are only part of the explanation for this situation, as large segments of the urban population in West Africa are not offered the public services, infrastructure and protective regulations needed in order to respond to floods. Through an empirically grounded approach, the article shows
that the ability to respond to floods is formed largely outside the realm of the state in a poor peri-urban municipality of Pikine, Dakar. The authors show how the organization of collective services pertaining to flood response and climate change adaptation is maintained through co-production among service users and providers entailing a mixture of diverse governance modes. The article concludes that weak state capacity is not equivalent to non-existent of ungoverned collective services linked to floods. While flood response service delivery through co-production, may constitute the best available options in a context of poor resources, because of the negotiated character of public service delivery it also creates an environment favourable for brokers to take ownership of central processes of service delivery and for structural inequalities to be reinforced locally.
On-road electric vehicle recharging infrastructure is essential in the transformation of electric vehicles into a practical transportation option. This study focuses upon assessing the need for recharging infrastructure for long distance travel for a large market share of electric vehicles, finding the optimal infrastructure deployment, and understanding the economic, social and environmental costs and benefits associated with the optimal infrastructure deployment. The analysis considers quick-charging and battery-switching as plausible recharging technologies. Results show: (i) the promotion of electric vehicles is beneficial when considering economic costs and benefits for operators and users, tax redistribution, and environmental externalities, even with a relatively modest market share; (ii) the number of required recharging stations for satisfaction of the travel demand is at the magnitude of 1–2% of the current gasoline infrastructure, under the assumption of wide availability of off-road recharging at home and the workplace; (iii) the optimal deployment of the recharging stations is along the main national highways outside of urban conurbations, under the assumption of wide availability of home recharging; (iv) the battery-switching technology is far more attractive to the consumer than the quick-charging technology for long-distance travel requiring more than one recharging visit.

The restricted stochastic user equilibrium with threshold model: Large-scale application and parameter testing
This paper presents the application and calibration of the recently proposed Restricted Stochastic User Equilibrium with Threshold model (RSUET) to a large-scale case-study. The RSUET model avoids the limitations of the well-known Stochastic User Equilibrium model (SUE) and the Deterministic User Equilibrium model (DUE), by combining the strengths of the Boundedly Rational User Equilibrium model and the Restricted Stochastic User Equilibrium model (RSUE). Thereby, the RSUET model reaches an equilibrated solution in which the flow is distributed according to Random Utility Theory among a consistently equilibrated set of paths which all are within a threshold relative to the cost on the cheapest path and which do not leave any attractive paths unused. Several variants of a generic RSUET solution algorithm are tested and calibrated on a large-scale case network with 18,708 arcs and about 20 million OD-pairs, and comparisons are performed with respect to a previously proposed RSUE model as well as an existing link-based mixed Multinomial Probit (MNP) SUE model. The results show that the RSUET has very attractive computation times for large-scale applications and demonstrate that the threshold addition to the RSUE model improves the behavioural realism, especially for high congestion cases. Also, fast and well-behaved convergence to equilibrated solutions among non-universal choice sets is observed across different congestion levels, choice model scale parameters, and algorithm step sizes. Clearly, the results highlight that the RSUET outperforms the MNP SUE in terms of convergence, calculation time and behavioural realism. The choice set composition is validated by using 16,618 observed route choices collected by GPS devices in the same network and observing their reproduction within the equilibrated choice sets generated by the RSUET model. Relevantly, the RSUET model is very successful in reproducing observed link.

The rise and fall of foreign private investment in the jatropha biofuel value chain in Ghana

The article draws on the multi-level perspective (MLP) and global value chain (GVC) frameworks to analyse the drivers and trajectories of foreign private investment in biofuel production in Ghana. It is based on a narrative of the evolution of a niche for jatropha production in Ghana in the period 1995 - 2016 including company case studies. The factors analysed relating to MLP are alignment of expectations, network formation, and learning and knowledge sharing, and those relating to GVC are chain structure, governance, ownership, and access to land and capital. High entry barriers for creating a new agriculture-based value chain for global biofuel markets, i.e. high volume requirements, high capital needs, and market risks contributed to the collapse of the jatropha sector in Ghana. A low level of learning and knowledge sharing between jatropha actors in Ghana, alongside weak public R&D support, reduced access to technical and managerial information. Confirming previous GVC research on biofuels, policy and NGOs had a stronger influence on the jatropha value chain than in typical agricultural chains. Moreover, global drivers and the strategies and capabilities of foreign investors can strongly influence the development of a new biofuel value chain in a developing country. The latter points complement previous research on jatropha, which highlights politicoeconomic factors such as land tenure, regional and local power relations, and the interests of donors and NGOs. The study exemplifies a nonevolutionary niche development that goes beyond the European experiences of industrial niche development on which the MLP framework was first established. The importance of investors and policy at different levels of the value chain illustrate the synergies in combining the MLP and GVC frameworks in research on energy transitions in developing countries.

The role of information systems in non-routine transit use of university students: Evidence from Brazil and Denmark

In this study we seek to understand the relation between travel information, transit use intentions and night travel. We hypothesize that transit use is related to the perceived usefulness and the ease-of-use of the system, which are related to information quality and real-time information availability. The hypothesized relations are anchored theoretically in the Technology Acceptance Model and validated empirically in two case-studies: (i) Copenhagen (Denmark), characterized by a highly integrated transit system with an advanced web-based information system; (ii) Recife and Natal (Brazil), characterized by a lower perceived level-of-service and non-integrated information sources. Data from a tailor-made...
survey of 1123 university students were collected. Structural equation models were employed for explaining the use of transit as a function of the observed respondent characteristics and the latent constructs. The results show that: (i) information search quality and source explain transit use; (ii) information quality underlies level-of-service and familiarity; (iii) the use of real-time information links to information quality and familiarity; (iv) general transit use and non-routine use during night and to unfamiliar places are correlated; and (v) the behavioral framework is confirmed with the two case-studies. The role of logbooks as mediators of engineering design work

Information transformation is key to engineering design work. However, research on how information management tools, and logbooks in particular, mediate this, is fragmented. We explore this via two studies (from which we confirm the central role of logbooks) and propose three modes of mediation: facilitating cognition and creation, gathering and collation of information, and staging and transformation of information. The findings explain the widespread use of logbooks through their support of these three modes. Consequently, we contend that multi-modal mediation is one of the main reasons why logbooks are such a central and enduring medium. This synthesises and extends theory on mediation and information use in engineering design. Further, practical insights are derived for the development new information management tools.

The role of natural resources in path development. The case of the bioeconomy

The last decade has witnessed a radical increase in attention to the bioeconomy, both in terms of academic research (Bugge, Hansen, & Klitkou, 2016) and policymaking (Richardson, 2012). Arguments in favour of a bioeconomy are often related to assumed positive effects in terms of addressing multiple grand challenges (Coenen, Hansen, & Rekers, 2015), in particular climate change, health and energy security (Ollikainen, 2014; Pützl, Kleinschmit, & Arts, 2014). However, opportunities for economic development associated with the transition to a bioeconomy are also repeatedly emphasised (Bugge et al., 2016; Pollack, 2012; Staffas, Gustavsson, & McCormick, 2013). Arguably, the bioeconomy necessitates and opens new opportunities for industrial development and restructuring, yet, a deeper understanding of these processes in the bioeconomy context is currently lacking. A central analytical perspective in economic geography to understand such industrial development processes is the concepts of path creation and path renewal. Insights from evolutionary economic geography have in particular highlighted that new industrial paths are likely to appear through a branching process where existing technological specialisations in regions condition future industrial diversification (Boschma & Frenken, 2012; Neffke, Henning, & Boschma, 2011). The underlying explanation is that localised knowledge spills over between technologically related fields and, thus, leads to new industry formation. While it is generally accepted in the literature that such regionally contained knowledge spillovers are important for path development processes, critiques have recently been raised concerning the lack of attention towards other potentially important factors. Thus, in addition to the existence of relevant knowledge, certain regions may also provide particularly fertile market conditions (Tanner, 2014) or support for new industries through the actions of public and quasi-public organisations (Dawley, 2014; Fornahl, Hassink, Klaerding, Mossig, & Schröder, 2012). Drawing on insights from the technological innovation systems literature, Binz, Truffer, and Coenen (2016) have suggested that path development processes are conditioned by the availability of four types of resources: knowledge, markets, finance and legitimacy. In the current paper, we seek to extend this line of reasoning in two ways. Firstly, we argue that the Binz et al. (2016) framework is insufficient for understanding path development processes in the bioeconomy because it ignores the role of natural resources. In general, evolutionary economic geography has paid little attention to the importance of natural resources. However, their availability may significantly influence path development processes in the bioeconomy as well as in other natural resource intensive industries. Secondly, we point to the inter-relation between the different forms of resources that condition path development processes, by outlining how natural resource availability influences the accessibility to other resources needed for bioeconomy path renewal. Empirically, we analyse path development in the forest industry in the South of Norway by examining on the process of turning a former pulp and paper mill near the city of Hønefoss into a production facility for multiple new wood-based products (i.e. a so-called biorefinery, see Bauer, Coenen, Hansen, McCormick, & Voytenko, 2016; Hansen & Coenen, 2016; OECD, 2009). The analysis is centred on a subsidiary, Treklyngen, of a large forest owner association, Viken Skog. The subsidiary was established in 2012 with the main goal of ensuring the establishment of new wood-based manufacturing at the site of the former pulp and paper mill. We used semi-structured interviews with central actors (Treklyngen, industry projects, politicians and stakeholder organisations), site visit, document analysis and media analysis as empirical data sources for conducting an event history analysis. Of central importance are events, which support or prevent access to resources (knowledge, markets, finance, legitimacy and natural resources). We also note
contextual events of importance in the political, economic and technological spheres. Thus, a database of events have been constructed, which documents the development of the Trekløsningen case from the origin in 2012 to the end of 2016. Preliminary findings are that the availability of natural resources was central to the path development process. As the traditional market for pulp and paper diminished, forest owners had to find new possibilities for value creation related to residues and pulp wood.

**The true cost of using traditional fuels in a humanitarian setting. Case study of the Nyarugusu refugee camp, Kigoma region, Tanzania**

Over the past two decades, the global number of forcibly displaced people has doubled, reaching 65.6 million in 2017. Reducing energy poverty has been identified as a priority on the international agenda since September 2015, when the UN adopted seventeen Sustainable Development Goals including Goal 7 which seeks to ‘ensure access to affordable, reliable, sustainable and modern energy for all by 2030’. However, recent research sheds light on the magnitude of energy poverty in humanitarian settings. In Sub-Saharan Africa, as much as 85% of the refugee population living in camps lack access to enough energy to cover their basic needs for cooking, heating and lighting. The inefficient use of energy by displaced people emitted 14.3 million tonnes of Carbon Dioxide (tCO2) in 2014, globally. The topic of humanitarian energy entails three aspects: the energy services (e.g. lighting, cooking or heating), the sources (solar, LPG, kerosene) and the products (solar panels, cookstoves, electricity grids) (RSC, 2017) (Gunning, 2014). Within this field, the provision of energy for cooking is a crucial dimension for many reasons. Firstly, because the food distributed by the World Food Program needs to be cooked, access to fuel underpins food security. Secondly, as many as 3.9 million people die every year from respiratory diseases associated with Household Air Pollution from cooking with solid fuels (Smith, 2014), which makes it the second most important environmental health risk factor after childhood malnourishment in Sub-Saharan Africa in terms of years due to ill-health (DALY) (Lim et al., 2012). This recognition even led to the creation of the UN-funded Global Alliance for Clean Cookstoves (GACC) in 2010. Finally, the encampment policy in Tanzania inevitably constrains firewood collection to small geographical areas, which often generates competition for resources and conflicts with the local communities.

**The use of electric vehicles: A case study on adding an electric car to a household**

The market share of battery electric vehicles (EVs) is expected to increase in the near future, but so far little is known about the actual usage of this emergent technology. Consumer preference studies have indicated that the current limitation on driving distance is important. At the same time studies on the actual use of household vehicles indicate modest requirements for daily travel. An unresolved issue is to what extent these range limitations affect daily travel in EVs. In this study, we use real electric vehicle trip data to study the distribution of daily use and types of home-based journeys where a household decides to use an electric vehicle instead of their conventional vehicle. The results show how several factors related to distance and number of necessary charging events have plausible effects on electric vehicle
travel behaviour. Further, the modelling indicates that the EV alternative is mostly used for well-planned transport and that EV use will not be the same as use of the conventional vehicle in two-vehicle households.

Time constrained liner shipping network design
We present a mathematical model and a solution method for the liner shipping network design problem. The model takes into account coordination between vessels and transit time restrictions on the cargo flow. The solution method is an improvement heuristic, where an integer program is solved iteratively to perform moves in a large neighborhood search. Our improvement heuristic is applicable as a real-time decision support tool for a liner shipping company. It can be used to find improvements to the network when evaluating changes in operating conditions or testing different scenarios. Computational results on the benchmark suite LINER-LIB are reported. Tolerance analysis for 0–1 knapsack problems

Post-optimal analysis is the task of understanding the behavior of the solution of a problem due to changes in the data. Frequently, post-optimal analysis is as important as obtaining the optimal solution itself. Post-optimal analysis for linear programming problems is well established and widely used. However, for integer programming problems the task is much more computationally demanding, and various approaches based on branch-and-bound or cutting planes have been presented. In the present paper, we study how much coefficients in the original problem can vary without changing the optimal solution vector, the so-called tolerance analysis. We show how to perform exact tolerance analysis for the 0–1 knapsack problem with integer coefficients in amortized time $O(c\log n)$ for each item, where $n$ is the number of items, and $c$ is the capacity of the knapsack. Amortized running times report the time used for each item, when calculating tolerance limits of all items. Exact tolerance limits are the widest possible intervals, while approximate tolerance limits may be suboptimal. We show how various upper bounds can be used to determine approximate tolerance limits in time $O(\log n)$ or $O(1)$ per item using the Dantzig bound and Dembo–Hammer bound, respectively. The running times and quality of the tolerance limits of all exact and approximate algorithms are experimentally compared, showing that all tolerance limits can be found in less than a second. The approximate bounds are of good quality for large-sized instances, while it is worth using the exact approach for smaller instances.

This article presents adaptive heuristics as an alternative approach to navigate uncertainty in project decision making. Adaptive heuristics are a class of simple decision strategies that have received only scant attention in project studies. Yet, they can strive in contexts of high uncertainty and limited information, which are the typical project decision context. This article develops a conceptual model that supports a systematic connection between adaptive heuristics and project decisions. Individual adaptive heuristics succeed only in specific decision environments, in which they are 'ecologically rational'. The model builds on the individual definitions of ecological rationality and organizes them according to two types of uncertainty ('knowable' and 'unknowable'). Decision problems and heuristics are furthermore grouped by decision task (choice and judgement). The article discusses several resulting propositions for future research and analyses the scant project literature on heuristics with regard to its fit to the model and the propositions. This conceptual approach supports future prescriptive research that can foster the development of efficient and intuitively applicable decision support tools. It finally highlights current boundaries of research on adaptive heuristics regarding the missing reflection of different types of uncertainty.

Towards harmonizing natural resources as an area of protection in life cycle impact assessment

In this paper, we summarize the discussion and present the findings of an expert group effort under the umbrella of the United Nations Environment Programme (UNEP)/Society of Environmental Toxicology and Chemistry (SETAC) Life Cycle Initiative proposing natural resources as an Area of Protection (AoP) in Life Cycle Impact Assessment (LCIA). As a first step, natural resources have been defined for the LCA context with reference to the overall UNEP/SETAC Life Cycle Impact Assessment (LCIA) framework. Second, existing LCIA methods have been reviewed and discussed. The reviewed methods have been evaluated according to the considered type of natural resources and their underlying principles followed (use-to-availability ratios, backup technology approaches, or thermodynamic accounting methods). There is currently no single LCIA method available that addresses impacts for all natural resource categories, nor do existing methods and models addressing different natural resource categories do so in a consistent way across categories. Exceptions are exergy and solar energy-related methods, which cover the widest range of resource categories. However, these methods do not link exergy consumption to changes in availability or provisioning capacity of a specific natural resource (e.g., mineral, water, land etc.). So far, there is no agreement in the scientific community on the most relevant type of future resource indicators (depletion, increased energy use or cost due to resource extraction, etc.). To address this challenge, a framework based on the concept of stock/fund/flow resources is proposed to identify, across natural resource categories, whether depletion/dissipation (of stocks and funds) or competition (for flows) is the main relevant aspect. An LCIA method—or a set of methods—that consistently address all natural resource categories is needed in order to avoid burden shifting from the impact associated with one resource to the impact associated with another resource. This paper is an important basis for a step forward in the direction of consistently integrating the various natural resources as an Area of Protection into LCA.
Toward Technology-Sensitive Catching-Up Policies: Insights from Renewable Energy in China

The voluminous literature on industrial catching-up in Southeast Asian countries has regularly argued that successful catching-up largely depended on a committed state, which orchestrated industry development with a relatively uniform set of policies, including R&D support, subsidies, trade restrictions, and local content requirements. In contrast, recent contributions from the technology lifecycle literature have argued that policies should be tailored to differing technological characteristics in industries for mass-produced standardized goods, complex engineered products, and—as we argue—complex product systems (CoPS). In this paper, we extend this argument by introducing a set of separate policy mixes for each industry type, which appears most capable of providing the key resources required for catching-up: knowledge, market access, financial investment and technology legitimacy. This framework is used to analyze catching-up patterns in China's wind, solar PV, and biomass power plant industries, drawing mainly on policy documents and 106 interviews with key industry actors. We find that traditional top-down catching-up policies played a decisive role in the development of China's wind industry, but were of limited importance in the early solar PV industry, and resulted only in a limited period of rapid growth in the biomass power plant industry. The relative progress achieved in these three industries is not related to top-down policy guidance alone, but also to private sector initiative, international interdependencies, and flexibility in adapting policy mixes to each industry's technological characteristics. These results suggest that policy makers in newly industrializing countries (NICs) should avoid drafting generic sector plans, but should tailor plans to individual industries,
and respond to changing policy support needs as technological capacities and global competitiveness develop.

Toward universal electrification in Ghana

In 1989, the government of Ghana set in motion an electrification plan that aims to provide universal access to electricity within a 30-year period, from 1990 to 2020. About 25 years down the line, Ghana seems to be inching closer toward universal electrification. However, a number of challenges remain. As is the case in many other countries, urban communities have greater access to the national electricity grid than rural communities. Also, electricity generation in the country has not matched demand. This has resulted in load shedding/power rationing that has become the bane of the power sector in Ghana, negatively impacting all sectors of the economy and leading to economic losses. The low generation capacity is partly due to poor fuel supply to existing thermal power plants, meaning that installed capacity is often not available for use. This is coupled with low investment in transmission and distribution systems’ infrastructure. Going forward, the government of Ghana would have to explore alternative ways of obtaining fuel, such as regasification, to solve the chronic issue of poor fuel supply for electricity generation. Distributed generation systems, using community mini-grid and off-grid systems are other alternatives that could be explored within the framework of the access agenda in order to reach the unserved poor located in remote rural communities.

Tramp ship routing and scheduling with voyage separation requirements

In this paper we explore tramp ship routing and scheduling. Tramp ships operate much like taxies following the available demand. Tramp operators can determine some of their demand in advance by entering into long-term contracts and then try to maximise profits from optional voyages found in the spot market. Routing and scheduling a tramp fleet to best utilise fleet capacity according to current demand is therefore an ongoing and complicated problem. Here we add further
complexity to the routing and scheduling problem by incorporating voyage separation requirements that enforce a minimum time spread between some voyages. The incorporation of these separation requirements helps balance the conflicting objectives of maximising profit for the tramp operator and minimising inventory costs for the charterer, since these costs increase if similar voyages are not performed with some separation in time. We have developed a new and exact branch-and-price procedure for this problem. We use a dynamic programming algorithm to generate columns and describe a time window branching scheme used to enforce the voyage separation requirements which we relax in the master problem. Computational results show that our algorithm in general finds optimal solutions very quickly and performs much faster compared to an earlier a priori path generation method. Finally, we compare our method to an earlier adaptive large neighbourhood search heuristic and find that on similar-sized instances our approach generally uses less time to find the optimal solution than the adaptive large neighbourhood search method uses to find a heuristic solution.

Transferring Knowledge from Building Operation to Design: A literature review

As a solution to the previously identified gap between expected and actual building performance, this paper investigates how knowledge can be transferred from operation to design. This is assumed to help bridge the gap and increase the performance of new built facilities. By conducting a systematic literature review, it is found, that the theoretical approach in the reviewed articles has a significant impact on the level of how applicable the recommendations are in practice. Furthermore, a list of identified tools to enable knowledge transfer is provided, including POE, PPP and building commissioning. Knowing that the list lacks inputs from cultural and organizational theory, the paper suggests that further research should focus on taking these suggestions to an operational level for the benefit of FM, building clients and design teams. Furthermore, it is found that major concepts that could be considered helpful to secure operational knowledge in design, such as Soft Landings and certification schemes like DGNB, are almost absent in the selected literature. This indicates that they are not recognized, and therefore not researched, as methods for knowledge transfer. Several countries, such as US, UK, Denmark, Saudi Arabia, and Malaysia are represented in the review.
Transport project evaluation: feasibility risk assessment and scenario forecasting

This paper presents a new approach to transport project assessment in terms of feasibility risk assessment and reference class forecasting. Conventionally, transport project assessment is based upon a Cost-Benefit Analysis (CBA) where evaluation criteria such as Benefit Cost Ratios (BCR) are obtained. Recent research has however proved that substantial inaccuracies are present when obtaining the monetary input to the CBA, particularly as concerns the construction costs and demand forecasts. This paper proposes a new approach in order to address these inaccuracies in a so-called Reference Scenario Forecasting (RSF) frame. The RSF is anchored in the cost-benefit analysis; thus, it provides decision-makers with a quantitative mean of assessing the transport infrastructure project. First, the RSF method introduces uncertainties within the CBA by applying Optimism Bias uplifts on the preliminary construction cost estimates. Hereafter, a quantitative risk analysis is provided making use of Monte Carlo simulation. This approach facilitates random input parameters based upon reference class forecasting, hence, a parameter data fit has been performed in order to obtain validated probability distribution functions. The latter have been placed and ultimately simulated on the inaccuracies of determining demand forecasts, i.e. leading to travel time savings and ticket revenues of the project. Finally, RSF makes use of scenario forecasting where trend scenarios such as economic growth and level of cross-border integration are investigated. The latter is highly relevant as RSF is demonstrated by a case example concerning the fixed link between Elsinore in Denmark and Helsingborg in Sweden.
UML Statechart Fault Tree Generation By Model Checking
Creating fault tolerant and efficient process workflows poses a significant challenge. Individual faults, defined as an abnormal conditions or defects in a component, equipment, or sub-process, must be handled so that the system may continue to operate, and are typically addressed by implementing various domain specific safeguards. In complex systems, individual faults may combine to give rise to system failure, defined as a state or condition of not meeting a desirable or intended objective. The safety analysis of such systems is labour-intensive and requires a key creative step where safety engineers imagine what undesirable events can occur under which conditions.

Fault Tree Analysis (FTA) attempts to analyse the failure of systems by composing logic diagrams of separate individual faults to determine the probability of larger compound faults occurring. FTA is a commonly used method to derive and analyse potential failures and their impact on overall system reliability and safety. FTA has seen extensive refinement and widespread adoption and is today considered a proven and accepted reliability engineering technique, often required for regulatory approval of systems. However, fault trees are typically manually constructed and determining the probabilities of faults occurring in systems which exhibit stochastic behaviour in the course of their correct execution is difficult, time-consuming and error prone.

Typically a FTA is based on an informal description of the underlying system, or requires modelling the system in an FTA specific language. This makes it difficult to check the consistency of the analysis, because it is possible that causes are noted in the tree which do not lead to the failure (incorrectness) or that some causes of failure are overlooked (incompleteness).

To avoid these deficiencies, our approach derives the fault tree directly from the formal system model, under the assumption that any state can fail.

We present a framework for the automated generation of fault trees from models of real-world process workflows, expressed in a formalised subset of the popular Business Process Modelling and Notation (BPMN) language. To capture uncertainty and unreliability in workflows, we extend this formalism with probabilistic non-deterministic branching. We present an algorithm that allows for exhaustive generation of possible error states that could arise in execution of the model, where the generated error states allow for both fail-stop behaviour and continuous system execution.

By employing stochastic model checking we calculate the probabilities of reaching each non-error state of the system. Each generated error state is assigned a variable indicating its individual probability of occurrence. Our method can determine the probability of combined faults occurring, while accounting for the basic probabilistic structure of the system being modelled. From these calculations, a comprehensive fault tree is generated. Further, we show that annotating the model with rewards (data) allows the expected mean values of reward structures to be calculated at points of failure.

Uncertainty Management and Sensitivity Analysis
Uncertainty is always there and LCA is no exception to that. The presence of uncertainties of different types and from numerous sources in LCA results is a fact, but managing them allows to quantify and improve the precision of a study and the robustness of its conclusions. LCA practice sometimes suffers from an imbalanced perception of uncertainties, justifying modelling choices and omissions. Identifying prevalent misconceptions around uncertainties in LCA is a central goal of this chapter, aiming to establish a positive approach focusing on the advantages of uncertainty management. The main objectives of this chapter are to learn how to deal with uncertainty in the context of LCA, how to quantify it, interpret and use it, and how to communicate it. The subject is approached more holistically than just focusing on relevant statistical methods or purely mathematical aspects. This chapter is neither a precise statistical method description, nor a philosophical essay about the concepts of uncertainty, knowledge and truth, although you will find a little bit of both. This chapter contains (1) an introduction of the essential terminology and concepts of relevance for LCA; (2) a discussion of main sources of uncertainty and how to quantify them; (3) a presentation of approaches to calculate uncertainty for the final results (propagation); (4) a discussion of how to use uncertainty information and how to take it into account in the interpretation of the results; and finally (5) a discussion of how to manage, communicate and present uncertainty information together with the LCA results.

Uniting individual and collective concerns through design: Priming across the senses
This paper contributes to design for behaviour change by testing the potential of priming via everyday products as a means of influencing users and dissolving conflicting individual and collective concerns. Self-construal is introduced as a core explanatory concept with respect to behaviours that unite individual and collective concerns. Two studies are reported. In the first, abstract representations of the target behaviour are elicited and incorporated into subconscious priming stimuli for each of the major senses: sight, hearing, touch, and smell. These primes are then evaluated in a controlled experiment. From these studies implications for both researchers and practitioners are identified. In particular, priming showed a significant effect across all senses.

Usage Frequency of Product Configuration Systems Relative to Integrations and Fields of Application

Product Configuration Systems (PCS) are automatic solutions that can support and facilitate the sales and engineering processes. PCSs have recently attracted increased attention both from the researches and practitioners. There are variety
of challenges reported in the literature as consequences of using PCS, which reduces the usage frequency of the system. To address those challenges, IT integrations can be an effective solution to reduce the number of manual tasks and complexity inside PCSs and make PCSs more user friendly. However, the influence of integrating PCS to different IT systems on usage frequency has not been addressed in the literature. This paper aims to study the relationship of PCS usage frequency in terms of (1) different application area of the PCSs, and (2) integrations to different IT systems. The research method adopted in the paper is survey-based conducted in one company where the unit of analysis is operating PCS.

Use of electric vehicles or hydrogen in the Danish transport sector in 2050?: Use of electric vehicles or hydrogen

Denmark has an ambitious long-term goal to reduce greenhouse gas (GHG) emissions from the transport sector with an overall climate target to be independent of fossil-fuel consumption by 2050. We compare a likely scenario with two alternative ways to achieve the goal—either with a high percentage of electric vehicles (EV) or with a high percentage of hydrogen use for transportation. The STREAM model—an energy scenario simulating tool—is used to model the different scenarios and their integration with the electricity and heating systems. The major findings are that an increased share of EV can reduce the socioeconomic cost of the energy system in 2050. However, electricity demand for H2 generation via electrolysis is more flexible than EV charging and the production can therefore, to a larger degree be used to out-balance variable electricity surplus from a high share of wind energy in the power system, reducing the investments in backup capacity. Whether the hydrogen scenario (H2S) is more costly to implement than the EV scenario (EVS) mainly depends on the technological development—especially the improvement on the efficiency of the conversion from electricity to H2 and the cost of the hydrogen fuel cell vehicle. Therefore, the major drivers of a successful H2S are a high efficient flexible H2 production in 2050 and lower vehicle costs, which increase the stability of the power grid, compared to the EVS. Hence, from a socioeconomic view point, the technological path in innovation to achieve fossil-free transport systems should have vehicle costs and electrolyzers efficiency as their main drivers toward 2050.

Use of Taxi-Trip Data in Analysis of Demand Patterns for Detection and Explanation of Anomalies

Because of environmental and economic stress, current strong investment in adaptive transport systems can efficiently use capacity, minimizing costs and environmental impacts. The common vision is of a system that dynamically changes itself (the supply) to anticipate the needs of travelers (the demand). In some occasions, unexpected and unwanted demand patterns are noticed in the traffic network; these patterns lead to system failures and cost implications. Significantly, low speeds or excessively low flows at an unforeseeable time are only some of the phenomena that are often noticed and need to be explained for a transport system to develop a better future response. The objective of this research was the formulation of a methodology that could identify anomalies on traffic networks and correlate them with special events by using Internet data. The main subject of interest in this study was the investigation of why traffic congestion was occurring as well as why demand fluctuated on days when there were no apparent reasons for such phenomena. The system was evaluated by using Google’s public data set for taxi trips in New York City. A “normality” baseline was defined at the outset and then used in the subsequent study of the demand patterns of individual days to detect outliers. With the use of this approach it was possible to detect fluctuations in demand and to analyze and correlate them with disruptive event scenarios such as extreme weather conditions, public holidays, religious festivities, and parades. Kernel density analysis was used so that the affected areas, as well as the significance of the observed differences compared with the average day, could be depicted.

USEtox® 2.0 Documentation (Version 1.00)
This document represents the official Documentation of USEtox, the United Nations Environment Programme (UNEP) / Society of Environmental Toxicology and Chemistry (SETAC) scientific consensus model for characterizing human and ecotoxicological impacts of chemical emissions in life cycle assessment. Main output of USEtox is a database of «recommended» and «indicative» characterization factors for human toxicity and freshwater ecotoxicity, based on modelling of environmental fate, exposure, and effect parameters for the substances. Due to deficiencies in the model or the available substance data, the «indicative» factors are accompanied by a higher uncertainty than the «recommended» factors, which should be considered when applying the factors and interpreting the results.
The latest official release version of USEtox is available at http://usetox.org

Using data- and network science to reveal iterations and phase-transitions in the design process

Understanding the role of iterations is a prevalent topic in both design research and design practice. Furthermore, the increasing amount of data produced and stored by companies leaves traces and enables the application of data science to learn from past design processes. In this article, we analyse a documentlog to show the temporal evolution of a real design process of a power plant by using exploratory data analysis and network analysis. We show how the iterative nature of the design process is reflected in archival data and how one might re-construct the design process, involving iterations between many parties, including the client, external consultants, suppliers, and designers. We also show how people use different representations during the design process and how this is associated with a design phase-transition in the process. Finally, we relate our findings with the literature on iterations and discuss implications for research and practice with application to project management and process modelling.

Using embedded design structures to unravel a complex decision in a product development system

Early design decisions have an impact on downstream product development processes. Poor decisions can reduce efficiency and effectiveness, and have a detrimental effect on product quality, delivery time, and cost. However, the range of tools suitable for use in early design is limited, in part because of ambiguity in available design definitions. This paper reports research that investigated the role of complex decision making in a quality incident that occurred in the development of a complex product system. A case study approach with document analysis and semi-structured interviews was used. Data were analysed using lenses from both social sciences and engineering design. In this paper, we report the use of embedded design structures to gain insights into the downstream consequences of design decisions. Results indicate that embedded product, process and supply network structures have the potential to underpin a new generation of design tools for considering downstream complexities arising from early design choices. Such tools could both improve the quality of design decisions and support improved management of development processes by highlighting areas of future risk.

Using Global Trends as Catalysts for City Transition

Urbanization process is triggered by population growth and technological advancement. Cities are accumulating global dynamics, gathering flows of people, energies and consequent risks. As a result, our habitat is facing a rapid transition [1]. City can use opportunities of momentum, planning and acting in response to the events or it can miss the chance, losing in the global competition. There is a considerable interest in finding, what influences city's prosperity. Global trends and the socio-demographic evolution are recognized as main overall powers. This study examines how these forces stimulate cities and how to employ them in a development process, in order to achieve a successful city transition. Searching for essential elements directing towards inclusive and successful city transition, the urbanization is studied. Global processes influence cities significantly with individual, different outcomes, what is examined in case study part. Case study provides cross sector analyses of three European cities, basing on national statistics, international and local databases. The study indicates that global forces and local conditions are of similar significance for city development. Case study illustrates divergence of outcomes generated by global forces. Therefore, a difficulty in building common approach, as there is no generic challenge-response. However, by identifying and mapping trends and patterns, inclusive and context-dependent strategy can be created appropriately, contributing to overall sustainability. While creating development strategies and future visions is a common practice, it lacks tools to identify the context-dependent factors. Specific conditions and patterns of city development are built in longtime perspective and the social short termism often counteracts improvement. To work with the overall forces city needs to recognize its unique situation. The current stage of urban development differs from city to city, what allows to make transferable learnings and stop repeating the same steps on the development path, regardless of their evaluation.

Using OR + AI to Predict the Optimal Production of Offshore Wind Parks: A Preliminary Study

In this paper we propose a new use of Machine Learning together with Mathematical Optimization. We investigate the question of whether a machine, trained on a large number of optimized solutions, can accurately estimate the value of the optimized solution for new instances. We focus on instances of a specific problem, namely, the offshore wind farm layout optimization problem. In this problem an offshore site is given, together with the wind statistics and the characteristics of the turbines that need to be built. The optimization wants to determine the optimal allocation of turbines to maximize the park power production, taking the mutual interference between turbines into account. Mixed Integer Programming models and other state-of-the-art optimization techniques, have been developed to solve this problem. Starting with a dataset of 2000+ optimized layouts found by the optimizer, we used supervised learning to estimate the production of new wind parks. Our results show that Machine Learning is able to well estimate the optimal value of offshore wind farm layout problems.

Value Chain Structures that Define European Cellulosic Ethanol Production

Production of cellulosic ethanol (CE) has not yet reached the scale envisaged by the literature and industry. This study explores CE production in Europe to improve understanding of the motivations and barriers associated with this situation. To do this, we conduct a case study-based analysis of CE production plants across Europe from a global value chain (GVC) perspective. We find that most CE production plants in the EU focus largely on intellectual property and are therefore only at the pilot or demonstration scale. Crescentino, the largest CE production facility in Europe, is also more interested in technology licensing than producing ethanol. Demonstration-scale plants tend to have a larger variety of feedstocks, whereas forestry-based plants have more diversity of outputs. As scale increases, the diversity of feedstocks and outputs diminishes, and firms struggle with feedstock provisioning, global petroleum markets and higher financial risks. We argue that, to increase CE production, policies should consider value chains, promote the wider bio-economy of products and focus on economics of scope. Whereas the EU and its member states have ethanol quotas and blending targets, a more effective policy would be to seek to reduce the risks involved in financing capital projects, secure feedstock provisioning and support a diversity of end products.

Value co-creation for FM innovation: Is it possible, and if yes, how?
No matter the industry, co-creation of value is a hot topic. Marketing specialists swear by it; manufacturers and service providers try to integrate it in their innovation practices; researchers study it. But what is value co-creation, and how does it apply to FM? Value co-creation is grounded in the recognition that firms are no longer in full charge of deciding upon the value to be offered to markets, but rather need to continuously cooperate with their customers, who become active collaborators in the creation of value. Value, in fact, is jointly created by supply and demand. The former offer the frame and resources for the co-creation of value, and the latter make their needs and expectations explicit and share their knowledge on how to satisfy them. In FM, value is created first and foremost by delivering and maintaining services that support the core business of organisations. According to the EN15221-1 definition, FM is "the integration of processes within an organization to maintain and develop (...) services which support and improve the effectiveness of its primary activities". In other words, FM is expected to create value for the organization it belongs to, by at least delivering and maintaining services that support the core business. Moreover, FM can add value by contributing to the organisational performance it belongs to (Voordt & Jensen, 2017).

**Viewpoint: Expand your career horizons with a position abroad**

It's job market season again. Are you sticking your toe in the water? Looking for a new challenge? A change of weather? Why not make a big splash and consider a position beyond your country’s borders? Of course, for decades institutions in English-speaking nations have filled their ranks with recruits from around the world, but rarely does an academic from an English-speaking nation make the move abroad.

**What is in a business case? Business cases as a tool-in-use for promoting water management practices in the food sector**

This paper explores the role of business cases as a tool for supporting decision-making processes regarding water management. Based on an analysis of survey and interview data from 300þ organisations within the European food sector, it is concluded that the relative emphasis on business cases and payback times influences the average level of water management engagement. However, the findings from the analysis also indicate that use of business cases are not set in stone but can be adapted and changed through ongoing dialogue and negotiations. The paper contributes to the existing academic literature by moving beyond generic discussions of the business case for corporate sustainability to exploring the concrete use of business cases as a decision-making tool for managers.

Given that the scope of stochastic programming is to suggest good decisions and not to estimate probability distributions, we demonstrate in this paper how to numerically evaluate which properties of random variables are more important to capture in a stochastic programming model. Such analysis, performed before data collection, can indicate which...
information should be primarily sought, and which is not critical for the final decision. We apply the analysis to a real-life instance of the maritime fleet renewal. Results show that some properties of the stochastic phenomena, such as the correlation between random variables, have very little influence on the final decision.

Which variety is free? Discerning the impact of product variety in the process industry

In the pursuit of mass customization, it is a great challenge for companies to maintain mass production efficiencies while producing a wide range of products. This poses an even greater challenge to process industry manufacturing systems which are built for high volume, low variety operations and which are sensitive to changes in process parameters. Many studies have been performed to quantify the impact of product variety on the efficiency of automotive assembly processes, but little work has been done to address process manufacturing systems. This study aims to determine the effects of individual product features on machine productivity at a process industry manufacturer. A lasso regression model is developed and tested using actual product and process level data from a stone wool manufacturer in central Europe. Results show that product features are less correlated to machine efficiency than process parameters, such as planning and crew performance.

Workspace experiments: a journey on planning participatory design

Summative Statement: This paper presents a resource material in planning and performing participatory workspace design processes. This material brings up design dialogues into focus and gives insights on how to stage them, bridging the gap of merging user involvement with the well-defined design work-practice. Problem statement: There is a widespread interest in implementing user involvement in major building and construction projects. Nevertheless, it is also often difficult to translate the contributions from users to workspace design that seriously take on board the employees' specific work practices as a platform for a desired change. There is a need of tool that manages to travel into a well-defined design work-practice and merge with it. Research Objective: We developed a resource material to merge user involvement within current designers' practices when designing new workplaces. The aim was to test how a participatory prototyping process can help developing such a material aimed at architects and other participants on workplace design projects. Methodology: We developed the resource material through a participatory “prototyping process”, that is through a mutual learning process taking place in a cooperative design setting. The material was gradually built during a research project, including three workshops emphasizing joint exploration by architects, consulting engineers and health & safety consultants. This method was used because we could discuss, explore, and try out various aspects of the new resource material with its prototypes and thus mediate communication among the different participants of the process, content and format being gradually developed through participation. Results: The result was a flexible resource material for designers as a tool to help building a participatory process specifically for each project. The material consists of a toolbox containing: 1) three booklets, 2) “playing” cards, 3) a game board, and 4) a leaflet explaining the main process the tool aims at bringing participants through. The booklets are the core of the toolbox and they aim at giving ideas and inspiration on methods and activities that can be part of the participatory process. The cards and the game board aim at making the use of the resource material a participatory and interactive activity in itself. The leaflet provides some guidance the participatory planning. Discussion: As we see it, the resource material was well accepted during a training section and some participants were happy they in fact used the time during the session to solve some planning issues for their
projects. The material became an asset that streamlined the planning of a participatory process while putting the key
topics within user involvement and workspace design on the agenda. It still has room for improvements, but it is a good
starting to introduce participatory methods into the design practices and to facilitate the planning for such activities.
Conclusions: The task of involving users in design processes is not easy and it can be a challenge to merge these
activities. The resource material helps staging the interventions and activities and preparing the materials to be used. On a
long term, we see the resource material as an open source, where new methods and inspiring ideas can always be added.

WW LCI v2: A second-generation life cycle inventory model for chemicals discharged to wastewater systems
We present a second-generation wastewater treatment inventory model, WW LCI 2.0, which on many fronts represents
considerable advances compared to its previous version WW LCI 1.0. WW LCI 2.0 is a novel and complete wastewater
inventory model integrating WW LCI 1.0, i.e. a complete life cycle inventory, including infrastructure requirement, energy
consumption and auxiliary materials applied for the treatment of wastewater and disposal of sludge and SewageLCI, i.e.
fate modelling of chemicals released to the sewer. The model is expanded to account for different wastewater treatment
levels, i.e. primary, secondary and tertiary treatment, independent treatment by septic tanks and also direct discharge to
natural waters. Sludge disposal by means of composting is added as a new option. The model also includes a database
containing statistics on wastewater treatment levels and sludge disposal patterns in 56 countries. The application of the
new model is demonstrated using five chemicals assumed discharged to wastewater systems in four different countries.
WW LCI 2.0 model results shows that chemicals such as diethylenetriamine penta (methylene phosphonic acid) (DTPMP)
and Diclofenac, exhibit lower climate change (CC) and freshwater ecotoxicity (FET) burdens upon wastewater treatment
compared to direct discharge in all country scenarios. Results for Ibuprofen and Acetaminophen (more readily degradable)
show that the CC burden depends on the country-specific levels of wastewater treatment. Higher treatment levels lead to
lower CC and FET burden compared to direct discharge. WW LCI 2.0 makes it possible to generate complete detailed life
cycle inventories and fate analyses for chemicals released to wastewater systems. Our test of the WW LCI 2.0 model with
five chemicals illustrates how the model can provide substantially different outcomes, compared to conventional
wastewater inventory models, making the inventory dependent upon the atomic composition of the molecules undergoing
treatment as well as the country specific wastewater treatment levels.

Development of Pathways to Achieve the SE4ALL Energy Efficiency Objective: Global and Regional Potential for Energy Efficiency Improvements

This study examines the three objectives of the UN Sustainable Energy for All (SE4ALL) initiative:
1. Ensure universal access to modern energy services by 2030.
2. Double the global rate of improvement in energy efficiency (from 1.3% to 2.6% annual reduction in energy intensity of GDP) by 2030.
3. Double the share of renewable energy in global final energy from 18% to 36% by 2030.

The integrated assessment model, ETSAP-TIAM, was used in this study to compare, from an economic optimization point of view, different scenarios for the development of the energy system between 2010 and 2030. This analysis is conducted on a global and regional scale. The scenarios were constructed to analyze the effect of achieving the SE4ALL energy efficiency objective, the SE4ALL renewable energy objective, both together, and all three SE4ALL objectives.

Synergies exist between renewable energy and energy efficiency. When the SE4ALL renewable energy objective is achieved, the economically optimal solution produced by ETSAP-TIAM also includes a reduction in energy intensity: globally, the compound annual reduction in energy intensity of GDP is 1.8% when the renewable energy objective is achieved. Likewise, a scenario that achieves the SE4ALL energy efficiency objective results in a solution that is halfway to the SE4ALL renewable energy objective: the 2030 global renewable energy share of total final energy is 26%. On a global scale, the renewable shares in every sector increase when the SE4ALL energy efficiency objective is achieved. The results from ETSAP-TIAM suggest that the SE4ALL energy access objective is not as synergetic with the other two objectives. When traditional biomass is phased out, the results show that it is more cost-effective to replace it with non-renewable energy sources for residential heating, cooking, and hot water.
Complexity Management - A multiple case study analysis on control and reduction of complexity costs

Complexity tends to be arguably the biggest challenge of manufacturing companies. The motivation of further studying complexity is a combination between the existing literature and the practical experiences from the industry. Based on the latest trend companies are trying to supply a growing mix of products, with features more custom-made to cover individual needs, both regarding characteristics of products and support services. This necessity leads to a considerable increase of the complexity in the company, which affects the product portfolio, production and supply chain, market segments, IT systems, and business processes. In order to identify and eliminate complexity, several approaches are used, both by researchers and practitioners. The purpose of this thesis is to contribute to the existing knowledge of complexity management theory. This research focuses on the relationship between product and process complexity. The possible factors for describing this correlation are identified and defined as complexity cost factors (CCFs). By identifying the CCFs this research intends to analyze the most relevant processes where the complexity and cost are directly related to the complexity of products. In this way, it will be possible to quantify the exact cost impact on those processes for each product variant. Furthermore, initiatives regarding complexity reduction are investigated. Standardization in product design, increased reusability of components, postponement of the customer order decoupling point (CODP) and utilization of configuration systems are further examined in terms of their complexity reduction effects. The research is supplemented with empirical evidence from several manufacturing companies. Finally, the evaluation of the obtained results indicates a strong managerial and theoretical potential for the control and reduction of complexity in manufacturing industries and pinpoints areas for further investigation.

Resilience Thinking as an Interdisciplinary Guiding Principle for Energy System Transitions

Resource usage and environmental consequences of most current energy systems exceed planetary boundaries. The transition to sustainable energy systems is accompanied by a multitude of research methods, as energy systems are complex structures of technical, economical, social and ecological interactions. The description of different discipline’s perspectives in this paper show that a more mutual understanding between disciplines of their respective focus is necessary as they partly create internally competitive views arising from differing emphasis of connected matters. The purpose of this paper is to present a framework for interdisciplinary proceeding in a complex energy system transition process. Resilience thinking is chosen as a core concept for a more holistic view on sustainable energy system development. It is shown that it is already widely used in different disciplines connected to energy system research and is especially suitable due to its wide application across disciplines. The seven principles of resilience thinking (maintain redundancy and diversity, manage connectivity, manage slow variables and feedback, foster complex adaptive systems thinking, encourage learning, broaden participation, and promote polycentric governance systems) are chosen as the basis for a procedure that can be utilized to increase the interdisciplinary perspectives of energy system transitions. For energy transition processes based on scenario development, backcasting and pathway definition, resilience thinking principles are used to assess the resilience of the target energy system, the pathway
resilience and the design of the scenario process with respect to the probability of a resilient outcome. The described procedure consisting of questions and parameters can be applied as a first attempt for a resilience assessment of energy transition processes. The perspective of resilience in sustainable energy systems strengthens the importance of diversity, redundancy and flexibility, which reduces the current dominant focus on efficiency of the overall system.

Black boxes on wheels: research challenges and ethical problems in MEA-based robotics
Robotic systems consisting of a neuron culture grown on a multielectrode array (MEA) which is connected to a virtual or mechanical robot have been studied for approximately 15 years. It is hoped that these MEA-based robots will be able to address the problem that robots based on conventional computer technology are not very good at adapting to surprising or unusual situations, at least not when compared to biological organisms. It is also hoped that insights gained from MEA-based robotics can have applications within human enhancement and medicine. In this paper, I argue that researchers within this field risk overstating their results by not paying enough attention to fundamental challenges within the field. In particular, I investigate three problems: the coding problem, the embodiment problem and the training problem. I argue that none of these problems have been solved and that they are not likely to be solved within the field. After that, I discuss whether MEA-based robotics should be considered pop science. Finally, I investigate the ethical aspects of this research.

Restructuring of workflows to minimise errors via stochastic model checking: An automated evolutionary approach

This article presents a framework for the automated restructuring of stochastic workflows to reduce the impact of faults. The framework allows for the modelling of workflows by means of a formalised subset of the BPMN workflow language. We extend this modelling formalism to describe faults and incorporate an intention preserving stochastic semantics able to model both probabilistic- and non-deterministic behaviour.

Stochastic model checking techniques are employed to generate the state-space of a given workflow. Possible improvements obtained by restructuring are measured by employing the framework's capacity for tracking real-valued quantities associated with states and transitions of the workflow. The space of possible restructurings of a workflow are explored by means of an evolutionary algorithm, where the goals for improvement are defined in terms of optimising quantities, typically employed to model resources, associated with a workflow.

The approach is fully automated and only the modelling of the production workflows, potential faults and the expression of the goals require manual input. We present the design of a software tool implementing this framework and explore the practical utility of this approach through an industrial case study in which the risk of production failures and their impact are reduced by restructuring the workflow.
A Benders Decomposition-Based Matheuristic for the Cardinality Constrained Shift Design Problem

The Shift Design Problem is an important optimization problem which arises when scheduling personnel in industries that require continuous operation. Based on the forecast, required staffing levels for a set of time periods, a set of shift types that best covers the demand must be determined. A shift type is a consecutive sequence of time periods that adheres to legal and union rules and can be assigned to an employee on any day. In this paper we introduce the Cardinality Constrained Shift Design Problem; a variant of the Shift Design Problem in which the number of permitted shift types is bounded by an upper limit. We present an integer programming model for this problem and show that its structure lends itself very naturally to Benders decomposition. Due to convergence issues with a conventional implementation, we propose a matheuristic based on Benders decomposition for solving the problem. Furthermore, we argue that an important step in this approach is finding dual alternative optimal solutions to the Benders subproblems and describe an approach to obtain a diverse set of these. Numerical tests show that the described methodology significantly outperforms a commercial mixed integer programming solver on instances with 1241 different shift types and remains competitive for larger cases with 2145 shift types. On all classes of problems the heuristic is able to quickly find good solutions. © 2016 Elsevier B.V.

Access over ownership: the case of meeting facilities in Lyngby

Collaborative Consumption, access economy or the sharing economy are all terms describing the new fast growing business built on the sharing of resources and promoting access over ownership. It is a paradigm shift that has made it to the Times magazine list of the "10 ideas that will change the world". Within this overall paradigm, shared space, is also gaining grounds. The purpose of the study is to investigate the attitude towards shared space in an urban context with a particular focus on meeting facilities. To what degree is there an interest in sharing meeting facilities within a city or a municipality? The Lyngby-Taarbæk City of Knowledge is used as case, as this strategic collaboration on municipal level includes a vision of sharing facilities to stimulate regional development. The attitude towards shared space in the Lyngby-Taarbæk City of Knowledge is studied in a three-step qualitative research process. The first survey investigates the City of Knowledge’s members attitude towards shared space in general with questions like, what are you most likely to share with others? And what would you like to gain access to? A workshop further explored motivations and practical needs. The second survey investigates in particular the attitude towards shared meeting facilities. The Brinkø Typology of Shared Use of Space and Facilities is used as the theoretical frame of the study (Brinkø et al 2015). This study show that the members of the Lyngby-Taarbæk City of Knowledge collaboration are very positive towards the concept of shared space, but more reluctant about sharing own facilities. A majority of the informants are often using externally owned facilities for meetings and events, and they prefer professional meeting facilities to schools, universities and sports facilities. This point to the need for buildings owners/operators to develop relevant service concepts, if a shared space strategy, should increase the use rate of existing buildings. The study show that in the Lyngby-Taarbæk City of Knowledge there is a positive attitude towards shared space as concept and as local strategy for gaining access to e.g. meeting facilities. The survey also demonstrates the member's experience of barriers, which suggest that there are practical barriers to overcome before access is more important than ownership, not only in theory, but also in practice.

Accounting for effect modifiers in ergonomic intervention research

Literature reviews suggest that tools facilitating the ergonomic intervention processes should be integrated into rationalization tools, particular if such tools are participative. Such a Tool has recently been developed as an add-in module to the Lean tool "Value Stream Mapping" (VSM). However, in the investigated context this module seems not to have any direct impact on the generation of proposals with ergonomic consideration. Contextual factors of importance seem to be e.g. allocation of sufficient resources and if work environment issues are generally accepted as part of the VSM methodology.
Accounting for the Theory of Planned Behaviour in departure time choice

Motivating people to change their departure time could play a key role in reducing peak hour congestion, which remains one of the most prevalent transport problems in large urban areas. To achieve this behavioural change, it is necessary to better understand the factors that influence departure time choice. So far, departure time choice modelling focused mainly on objective factors, such as time and costs as main behavioural determinants. In this study, we derived psychological factors based on the Theory of Planned Behaviour, estimated them based on structural equation modelling, and included them into a discrete choice model. The psychological factors were measured based on an online questionnaire addressed to car commuters to the city centre of Copenhagen (N = 286). The questionnaire additionally included a travel diary and a stated preference experiment with nine departure time choice scenarios. All psychological factors had a significant effect on departure time choice and could improve the model as compared to a basic discrete choice model without latent constructs. As expected, the effects of the psychological factors were different depending on framework conditions: for people with fixed starting times at work, the intention to arrive at work on time (as estimated by subjective norm, attitude, perceived behavioural control) had the strongest effect; for people with flexible working hours, the attitude towards short travel time was most relevant. Limitations, the inclusion of additional psychological factors and their possible interactions are discussed.

A comparison of two exact methods for passenger railway rolling stock (re)scheduling

The assignment of rolling stock units to timetable services in passenger railways is an important optimization problem that has been addressed by many papers in different forms. Solution approaches have been proposed for different planning phases: strategic, tactical, operational, and real-time planning. In this paper we compare two approaches within the operational and real-time planning phase. The first exact approach is based on a known Mixed Integer Linear Program (MILP) which is solved using CPLEX. The second approach is a new method that is an extension of a recently introduced MILP, which is solved using a column and row generation approach. In this paper, we benchmark the performance of the methods on networks of two countries (Denmark and The Netherlands). We use the approaches to make daily schedules and we test their real time applicability by performing tests with different disruption scenarios. The computational experiments demonstrate that both models can be used on both networks and are able to find optimal rolling stock circulations in the different planning phases. Furthermore, the results show that both approaches are sufficiently fast to be used in a real-time setting.
A consistent framework for modeling inorganic pesticides: Adaptation of life cycle inventory models to metal-base pesticides

Quantifying over the life cycle of a product or service the chemical emissions to the environment in the life cycle inventory (LCI) phase is typically based on generic assumptions. Regarding the LCI application to agricultural systems the estimation of pesticide emissions is often based on standard emission factors (percentages) or dynamic models base on specific application scenarios that describe only the behavior of organic pesticides. Currently fixed emission fractions for pesticides dearth to account for the influence of pesticide-specific function to crop type and application methods. On the other hand the dynamic models need to account for the variability in this interactions in emissions of inorganic pesticides. This lack of appropriate models to estimate emission fractions of inorganic pesticides results in a lower accuracy when accounting for emissions in agriculture, and it will influence the outcomes of the impact profile. The pesticide emission model PestLCI 2.0 is the most advanced currently available inventory model for LCA intended to provide an estimation of organic pesticide emission fractions to the environment. We use this model as starting point for quantifying emission of inorganic pesticides and customize it taking into account the complex chemistry of metals in order to properly reflect the their environmental fate behavior. We identified specific needs for metal-specific pesticides emission modeling looking at the current PestLCI structure and propose an approach for the different metal-related processes and interactions. The proposed framework takes into consideration the speciation of the metals to accurately describe the soil processes (runoff and leaching). The processes involving degradation are assumed not significant for metals and volatilization is only accounted for special cases (i.e. mercury). And finally, a new module of erosion is included in the modified PestLCI model, because the transport of soil particles to which the metals are bound needs to be considered as potential source of emissions to surface water. In conclusion, we provide a starting point to better estimate metal-specific pesticide emission fractions, addressing the issue of inorganic pesticides for inventory analysis in LCA of agricultural systems.
Active thermography and post-processing image enhancement for recovering of abraded and paint-covered alphanumeric identification marks

Alphanumeric marking is a common technique employed in industrial applications for identification of products. However, the realised mark can undergo deterioration, either by extensive use or voluntary deletion (e.g. removal of identification numbers of weapons or vehicles). For recovery of the lost data many destructive or non-destructive techniques have been endeavoured so far, which however present several restrictions. In this paper, active infrared thermography has been exploited for the first time in order to assess its effectiveness in restoring paint covered and abraded labels made by means of different manufacturing processes (laser, dot peen, impact, cold press and scribe). Optical excitation of the target surface has been achieved using pulse (PT), lock-in (LT) and step heating (SHT) thermography. Raw infrared images were analysed with a dedicated image processing software originally developed in Matlab™, exploiting several methods, which include thermographic signal reconstruction (TSR), guided filtering (GF), block guided filtering (BGF) and logarithmic transformation (LN). Proper image processing of the raw infrared images resulted in superior contrast and enhanced readability. In particular, for deeply abraded marks, good outcomes have been obtained by application of logarithmic transformation to raw PT images and block guided filtering to raw phase LT images. With PT and LT it was relatively easy to recover labels covered by paint, with the latter one providing better thermal contrast for all the examined targets. Step heating thermography never led to adequate label identification instead.
Activity-based Sustainability Assessment of Highly Automated Manufacturing

Sustainability of technology is a multifaceted endeavor and a main requirement from industry is to make it a profitable business case with clearly defined targets. To achieve that, a new assessment framework and applicable method [1] is presented which has been developed closely with industry. It uses a top-down decision-making process known from financial target setting for each cost center and the well-known life-cycle perspective according to ISO 14040 [2] in Sustainability Assessment. Thereby it is possible to allocate absolute environmental thresholds of functionalities (e.g. “transportation”) down to smallest production units by using activity-based target setting in a consistent way to lowers risks in the planning phase of products and production.

Adding Value to Facilities Management with Information Technology
This PhD project investigates implementation and use of Information Systems (IS) and Information Technologies (IT) in the Facilities management (FM) business domain. This investigation is relevant because implementation and use of IS/IT in FM has potentials for improvements which can provide additional value to FM and the organisations which FM supports. The empirical data was collected from more than 16 IS implementation and use cases in FM departments within private and public organisations in Denmark, Sweden, Germany and Australia. Data from 5 of the 16 cases are used as main input to the analysis in this study. The cases have revealed a common structure of the elements constituting the IS and the Business Processes (BP) which the IS are intended to support. Based on this structure an IS-BP framework for analysing the interaction between Business Strategy, BP and the IS supporting the BP is proposed. Specific issues are studied concerning the implementation processes, such as IS project scope, and formal control mechanisms used on the organisational IS level and on the IS project level. Also issues related to the change taking place such as the added value of IS implementation are studied. Finally IS strategy as the strategy of the use of IS to support business strategy (BS) is studied.

Addressing Climate Change Mitigation and Adaptation Together: A Global Assessment of Agriculture and Forestry Projects
Adaptation and mitigation share the ultimate purpose of reducing climate change impacts. However, they tend to be considered separately in projects and policies because of their different objectives and scales. Agriculture and forestry are related to both adaptation and mitigation: they contribute to greenhouse gas emissions and removals, are vulnerable to climate variations, and form part of adaptive strategies for rural livelihoods. We assessed how climate change project design documents (PDDs) considered a joint contribution to adaptation and mitigation in forestry and agriculture in the tropics, by analyzing 201 PDDs from adaptation funds, mitigation instruments, and project standards [e.g., climate community and biodiversity (CCB)]. We analyzed whether PDDs established for one goal reported an explicit contribution to the other (i.e., whether mitigation PDDs contributed to adaptation and vice versa). We also examined whether the proposed activities or expected outcomes allowed for potential contributions to the two goals. Despite the separation between the two goals in international and national institutions, 37 % of the PDDs explicitly mentioned a contribution to the other objective, although only half of those substantiated it. In addition, most adaptation (90 %) and all mitigation PDDs could potentially report a contribution to at least partially to the other goal. Some adaptation project developers were interested in mitigation for the prospect of carbon funding, whereas mitigation project developers integrated adaptation to achieve greater long-term sustainability or to attain CCB certification. International and national institutions can provide incentives for projects to harness synergies and avoid trade-offs between adaptation and mitigation.

Advancing absolute sustainability assessments of products with a new Planetary Boundaries based life-cycle impact assessment methodology

The Planetary Boundaries (PB)-framework introduced quantitative boundaries for a set of biophysical Earth System processes. The PBs delimit a ‘safe operating space’ for humanity to act within to keep Earth in a Holocene-like state (Rockström et al 2009). The concept has gained strong interest from companies that want to assess and communicate the environmental sustainability of their products relative to the PBs. However, consistent methods for assessing environmental impacts of products and systems based on the PBs have, to date, not been developed (Ryberg et al 2016).

In this study, we developed an operational life-cycle impact assessment (LCIA) methodology where the definition of the impact categories is based on the control variables as defined in the PB-framework by Steffen et al (2015). This included the development and calculation of characterization factors for the Earth System processes considered in the PB-framework. The characterization factors cover environmental flows contributing to impacts on the Earth System processes (e.g. CO2 and its precursors contributing to ocean acidification) and are expressed in the units of the PB-framework’s control variables (e.g. change in the aragonite saturation state per unit CO2 emission for ocean acidification). The use of these characterization factors for evaluating the environmental impacts of products in LCA ensures impact scores that are compatible with the PB framework. The impact scores can be related to either the full PBs or an allocated safe operating space. The latter reflect the share of the safe operating space the assessed products can be considered entitled to, thereby, allowing for quantifying the absolute environmental sustainability of the products.

This new Planetary Boundaries based LCIA methodology provides additional and complementary insights which cannot be achieved with traditional LCIA methodologies. The key added value is the ability to relate the impacts of a product to the Planetary Boundaries. This can be used for communicating a product’s environmental performance and for setting reduction targets based on absolute environmental boundaries, thereby, advancing absolute sustainability assessments.

A flexible matrix-based human exposure assessment framework suitable for LCA and CAA

Humans can be exposed to chemicals via near-field exposure pathways (e.g. through consumer product use) and far-field exposure pathways (e.g. through environmental emissions along product life cycles). Pathways are often complex where chemicals can transfer directly from products to humans during use or exchange between near- and far-field compartments until sub-fractions reach humans via inhalation, ingestion or dermal uptake. Currently, however, multimedia exposure models mainly focus on far-field exposure pathways. Metrics and modeling approaches used in far-field, emission-based models are not applicable to all types of near-field chemical releases from consumer products, e.g. direct dermal application. A consistent near-and far-field framework is needed for life cycle assessment (LCA) and chemical alternative assessment (CAA) to inform mitigation of human exposure to harmful chemicals. To close the current research gaps, we (i) define a near-and far-field matrix-based exposure pathways framework that builds on a quantitative metric based on chemical mass in products, (ii) provide input data for the framework, e.g. chemical concentrations in products linked to functional use categories, and (iii) propose a consistent set of underlying models to populate the matrix-based framework for all relevant multimedia transfers and exposure pathways. Output is a flexible mass balance-based model structuring multimedia transfers in a matrix of first-order inter-compartmental transfer fractions. Inverting this matrix yields cumulative multimedia transfer fractions and exposure pathway-specific Product Intake Fractions defined as chemical mass taken in by humans per unit mass of chemical in a product. When the chemical mass in products is unavailable from individual studies and databases, it can be estimated from chemical-product function relationships or regulatory frame formulations. Combining Product Intake Fractions with chemical masses in products yields exposure estimates per unit mass compatible with LCA and CAA. We demonstrate how this matrix-based modeling system offers a consistent and efficient way to compare exposure pathways for different user groups (e.g. children and adults) and the general population exposed via the environment associated with product use. Our framework constitutes a user-friendly approach to test and interpret multiple human exposure scenarios in a coupled system of near- and far-field pathways and helps to understand the contribution of individual pathways to overall human exposure in various product application contexts. When combined with toxicity information this approach is a resourceful way to inform LCA and CAA and minimize human exposure to toxic chemicals in consumer products through both product use and environmental emissions.
Age and attitude: Changes in cycling patterns of different e-bike user segments

The use and purchase of electric bicycles (e-bikes) is emerging in many countries. Existing knowledge about changes in cycling patterns and car replacement after gaining e-bike access is limited and partly contradictory. Based on an online survey among e-bike users in Denmark (N = 427), this study looked into these effects by differentiating between different segments of e-bike users. We distinguished four age groups as well as three segments based on cycling attitudes and motives for the use and purchase of e-bikes: (1) enthusiastic e-bikers who showed the most positive attitudes towards e-bikes and mainly bought an e-bike to increase cycling frequency; (2) utilitarian e-bikers who already cycled regularly before having access to an e-bike and used the e-bike particularly for practical purposes and to reduce travel time; (3) recreational e-bikers who were very positive about e-bike use but used it less regularly and mainly for long-distance recreational trips. Enthusiastic e-bikers reported the highest increase in overall cycling. Half of the enthusiastic e-bikers agreed that they bought the e-bike to replace a car. Differences between the four age groups were less pronounced. Nevertheless, we found that e-bike access decreased age differences in self-reported cycling frequency, whereas it increased differences in self-reported distances. Measures to increase e-bike use should primarily focus on potential enthusiastic e-bikers. Possible interventions include promotional campaigns at workplaces, intended to address not only instrumental but also affective motives of e-bike use.
A GRASP algorithm for the container stowage slot planning problem

This work presents a generalization of the Slot Planning Problem which raises when the liner shipping industry needs to plan the placement of containers within a vessel (stowage planning). State-of-the-art stowage planning relies on a heuristic decomposition where containers are first distributed in clusters along the vessel. For each of those clusters a specific position for each container must be found. Compared to previous studies, we have introduced two new features: the explicit handling of rolled out containers and the inclusion of separations rules for dangerous cargo. We present a novel integer programming formulation and a Greedy Randomized Adaptive Search Procedure (GRASP) to solve the problem. The approach is able to find high-quality solution within 1 s. We also provide comparison with the state-of-the-art on an existing and a new set of benchmark instances. (C) 2016 Elsevier Ltd. All rights reserved.

A heuristic and hybrid method for the tank allocation problem in maritime bulk shipping

In bulk shipping, ships often have multiple tanks and carry multiple inhomogeneous products at a time. When operating such ships it is therefore a major challenge to decide how to best allocate cargoes to available tanks while taking into account tank capacity, safety restrictions, ship stability and strength as well as other operational constraints. The problem of finding a feasible solution to this tank allocation problem has been shown to be NP-Complete. We approach the problem on a tactical level where requirements for computation time are strict while solution quality is less important than simply finding a feasible solution. We have developed a heuristic that can efficiently find feasible cargo allocations. Computational results show that it can solve 99% of the considered instances within 0.4 s and all of them if allowed longer time. We have also modified an optimality based method from the literature. The heuristic is much faster than this modified method on the vast majority of considered instances. However, the heuristic struggles on two instances which are relatively quickly solved by the modified optimality based method. These two methods therefore complement each other nicely and so, we have created a hybrid method that first runs the heuristic and if the heuristic fails to solve the problem, then runs the modified optimality based method on the parts of the problem that the heuristic did not solve. This hybrid method cuts between 90 and 94% of the average running times compared to the other methods and consistently solves more instances than the other methods within any given time limit. In fact, this hybrid method is fast enough to be used in a tactical setting.
A hybrid ICT-solution for smart meter data analytics

Smart meters are increasingly used worldwide. Smart meters are the advanced meters capable of measuring energy consumption at a fine-grained time interval, e.g., every 15 min. Smart meter data are typically bundled with social economic data in analytics, such as meter geographic locations, weather conditions and user information, which makes
The data sets very sizable and the analytics complex. Data mining and emerging cloud computing technologies make collecting, processing, and analyzing the so-called big data possible. This paper proposes an innovative ICT-solution to streamline smart meter data analytics. The proposed solution offers an information integration pipeline for ingesting data from smart meters, a scalable platform for processing and mining big data sets, and a web portal for visualizing analytics results. The implemented system has a hybrid architecture of using Spark or Hive for big data processing, and using the machine learning toolkit, MADlib, for doing in-database data analytics in PostgreSQL database. This paper evaluates the key technologies of the proposed ICT-solution, and the results show the effectiveness and efficiency of using the system for both batch and online analytics.
Airbags til cyklister

En cykelhjelms størrelse og tykkelse er afgørende for dens evne til at dæmpe det stød som cyklister udsættes for i forbindelse med styrt og/eller kollision. Både praktisk og æstetisk er der dog grænser for, hvor stor en hjelm cyklister vil cykle rundt med. En gruppe amerikanske forskere har testet en ny type cykelhjelm, der udvider sig i forbindelse med styrt/kollision. Forskerne konkluderer, at den nye hjelmtype har potentiale til god beskyttelse mod hovedskader, men at der er behov for en omfattende forskningsindsats før der kan konkluderes endeligt vedrørende den trafiksikkerhedsmessige effekt.

A life cycle assessment framework combining nutritional and environmental health impacts of diet: a case study on milk

Purpose While there has been considerable effort to understand the environmental impact of a food or diet, nutritional effects are not usually included in food-related life cycle assessment (LCA).

Methods We developed a novel Combined Nutritional and Environmental Life Cycle Assessment (CONE-LCA) framework that evaluates and compares in parallel the environmental and nutritional effects of foods or diets. We applied this framework to assess human health impacts, expressed in Disability Adjusted Life Years (DALYs), in a proof-of-concept case study that investigated the environmental and nutritional human health effects associated with the addition of
one serving of fluid milk to the present average adult US diet. Epidemiology-based nutritional impacts and benefits linked to milk intake, such as colorectal cancer, stroke, and prostate cancer, were compared to selected environmental impacts traditionally considered in LCA (global warming and particulate matter) carried to a human health endpoint. **Results and discussion** Considering potential human health effects related to global warming, particulate matter, and nutrition, within the context of this study, findings suggest that adding one serving of milk to the current average diet could result in a health benefit for American adults, assuming that existing foods associated with substantial health benefits are not substituted, such as fruits and vegetables. The net health benefit is further increased when considering an iso-caloric substitution of less healthy foods (sugar-sweetened beverages). Further studies are needed to test whether this conclusion holds within a more comprehensive assessment of environmental and nutritional health impacts. **Conclusions** This case study provides the first quantitative epidemiology-based estimate of the complements and trade-offs between nutrition and environment human health burden expressed in DALYs, pioneering the infancy of a new approach in LCA. We recommend further testing of this CONE-LCA approach for other food items and diets, especially when making recommendations about sustainable diets and food choices.

A life-cycle assessment of poly-hydroxybutyrate extraction from microbial biomass using dimethylcarbonate

Plastic materials have wide commercial applicability. However, they are made from non-renewable resources and are characterised by resistance to degradation. Poly-hydroxyalkanoates (PHAs) provides one example of a polymer biodegradable, biocompatible and produced from renewable raw materials. With respect to other bioplastics the share of PHAs in the market is very limited because of their commercial costs. To develop more cost effective processes for PHAs production, a multilevel approach is usually undertaken combining innovative, cheaper and more effective cultivation with safe and cheap extraction and purification methodologies. This study assesses the potential environmental impacts related to a production processes based on the novel protocol to extract PHAs comparing them to the impacts of extraction process based on the use of halogenated hydrocarbons.

Almost like being there; the Power of Personas when designing for foreign Cultures

Much research on personas focuses on how to develop and use personas, less on the validation and concrete value of them in the development of products for cultures far away from the actual design site. This article illustrates how such a validation was accomplished through producing a film and it provides an in-depth case description of how personas were developed and used. When designing a waste management system for soft plastic for a small village in India, personas
were developed and applied by the designer to maintain a user-oriented focus throughout the participatory design process. During a three-month stay in the village, personas based on real people and the villagers’ everyday life and practices were developed by getting to know people and their ways of life through the use of ethnographic methods (observations, interviews, workshops and a film). The personas created a substantial understanding of the users’ individual needs, interests, values and emotions and helped to overcome the physical and cultural distance, enabling a strongly contextualised design.

Alternatives for Future Waste Management in Denmark: Final Report of TopWaste

The TOPWASTE project has addressed the challenges of planning robust solutions for future waste management. The purpose was to identify economic and environmentally optimal solutions - taking into account different scenarios for the development of the surrounding systems, such as the energy system. During the project, four decision support tools were developed: 1. Frida - The EPA's tool for forecasting future waste generation 2. OptiWaste - a new tool for economic optimisation of investments and operation of the combined waste and energy system 3. KISS - a new lifecycle based model with focus on comparison of greenhouse gas emissions associated with different waste management alternatives 4. A new tool for techno-economic modelling of central sorting plants.

The project has furthermore contributed with method development on evaluation of critical resources as well as analyses of economic and organisational factors with influence on the future waste management. The results of the project clearly show the importance of taking scenarios for the future development of surrounding systems into account when deciding how the future waste management should be, both when it comes to the economic, environmental and resource efficiency of waste management solutions. The following chapters addresses these issues by answering some of the main research questions of the project.

A Matheuristic Approach to Integrate Humping and Pullout Sequencing Operations at Railroad Hump Yards

This article presents a novel matheuristic for solving the hump yard block-to-track assignment problem. This is an important problem arising in the railway freight industry and involves scheduling the transitions of a set of rail cars from a set of inbound trains to a set of outbound trains over a certain planning horizon. It was also the topic of the 2014 challenge organized by the Railway Applications Section of the Institute for Operations Research and the Management Sciences for which the proposed matheuristic was awarded first prize. Our approach decomposes the problem into three highly dependent subproblems. Optimization-based strategies are adopted for two of these, while the third is solved using a
greedy heuristic. We demonstrate the efficiency of the complete framework on the official datasets, where solutions within 4–14% of a known lower bound (to a relaxed problem) are found. We further show that improvements of around 8% can be achieved if outbound trains are allowed to be delayed by up to 2 h in the hope of ensuring an earlier connection for some of the rail cars. © 2015 Wiley Periodicals, Inc.

A Maturity Grid Assessment Tool for Environmentally Conscious Design in the Medical Device Industry
The medical device industry is growing increasingly concerned about environmental impact of products. Whilst there are many tools aiming to support environmentally conscious design, they are typically complex to use, demand substantial data collection and are not tailored to the specific needs of the medical device sector. This paper reports on the development of a Maturity Grid to address this gap. This novel design tool was developed iteratively through application in five case studies. The tool captures principles of eco-design for medical devices in a simple form, designed to be used by a team. This intervention tool provides designers and product marketers with insights on how to improve the design of their medical devices and specifically allows consideration of the complex trade-offs between decisions that influence different life-cycle stages. Through the tool, actionable insight is created that supports decisions to be made within the realm of design engineers and beyond. The tool highlights areas which are influenced by design decisions taken, some of which are perceived to be outside of the direct control of designers.

A method for aggregating external operating conditions in multi-generation system optimization models

This paper presents a novel, simple method for reducing external operating condition datasets to be used in multi-generation system optimization models. The method, called the Characteristic Operating Pattern (CHOP) method, is a visually-based aggregation method that clusters reference data based on parameter values rather than time of occurrence, thereby preserving important information on short-term relations between the relevant operating parameters. This is opposed to commonly used methods where data are averaged over chronological periods (months or years), and extreme conditions are hidden in the averaged values. The CHOP method is tested in a case study where the operation of a fictive Danish combined heat and power plant is optimized over a historical 5-year period. The optimization model is solved using the full external operating condition dataset, a reduced dataset obtained using the CHOP method, a monthly-averaged dataset, a yearly-averaged dataset, and a seasonal peak/off-peak averaged dataset. The economic result obtained using the CHOP-reduced dataset is significantly more accurate than that obtained using any of the other reduced datasets, while the calculation time is similar to those obtained using the monthly averaged and seasonal peak/off-peak averaged datasets. The outcomes of the study suggest that the CHOP method is advantageous compared to chronology-averaging methods in reducing external operating condition datasets to be used in the design optimization models of flexible multi-generation systems.

A method for Effect Modifier Assessment in ergonomic intervention research – The EMA method

Introduction:
Ergonomic intervention research includes studies in which researchers arrange (or follow) changes in working conditions to determine the effects in risk factors and/or health. Often this research takes place at workplaces and not in a controlled environment of a laboratory. The effects may thus be due to other factors in addition to the investigated intervention – i.e. due to effect modifiers. Such effect modifiers need to be identified and assessed in terms of potential impact on the investigated outcome before proper inference can be drawn. A preliminary review of the literature revealed lack of or poor consideration of effect modifiers in ergonomic intervention research. We present a method that has been developed over the course of several years parallel to intervention studies in healthcare.

Material and methods:
The EMA method is a type of group interview including 3-6 employees representing the occupational groups in the investigated organization. With reference to the investigated period they are asked to recall important changes/events in and around the ward; 1) in general, 2) in work processes and equipment and 3) regarding their work environment. In each step the participants write their individual answer on post-it notes. The answers are then discussed in plenum, one at a time, and the post-it note is placed on a timeline. At the end this illustrates the sequence of significant events. All identified events are assessed for being caused by either the investigated intervention(s) or other causes ("the effect modifiers") and their impact on the work environment. Following the workshop, events are entered into a database and reassessed by triangulation based on scientific evidence, researcher knowledge, reading the transcribed audio recorded workshop and other local sources.

Conclusion:
The EMA method seems to offer a feasible procedure to obtain significant knowledge on potential effect modifiers in ergonomic intervention research. However, further development and validation is suggested.

A methodology for designing flexible multi-generation systems

An FMG (flexible multi-generation system) consists of integrated and flexibly operated facilities that provide multiple links between the various layers of the energy system. FMGs may facilitate integration and balancing of fluctuating renewable energy sources in the energy system in a cost- and energy-efficient way, thereby playing an important part in smart energy systems.

The development of efficient FMGs requires systematic optimization approaches. This study presents a novel, generic methodology for designing FMGs that facilitates quick and reliable pre-feasibility analyses. The methodology is based on consideration of the following points: Selection, location and dimensioning of processes; systematic heat and mass integration; flexible operation optimization with respect to both short-term market fluctuations and long-term energy system development; global sensitivity and uncertainty analysis; biomass supply chains; variable part-load performance; and multi-objective optimization considering economic and environmental performance.

Tested in a case study, the methodology is proved effective in screening the solution space for efficient FMG designs, in assessing the importance of parameter uncertainties and in estimating the likely performance variability for promising designs. The results of the case study emphasize the importance of considering systematic process integration when developing smart energy systems.
A methodology to measure the effectiveness of academic recruitment and turnover

We propose a method to measure the effectiveness of the recruitment and turnover of professors, in terms of their research performance. The method presented is applied to the case of Italian universities over the period 2008–2012. The work then analyses the correlation between the indicators of effectiveness used, and between the indicators and the universities’ overall research performance. In countries that conduct regular national assessment exercises, the evaluation of effectiveness in recruitment and turnover could complement the overall research assessments. In particular, monitoring such parameters could assist in deterring favoritism, in countries exposed to such practices. © 2015 Elsevier Ltd. All rights reserved.
A model of designing as the intersection between uncertainty perception, information processing, and coevolution

A number of fundamental perspectives on designing have been described in the literature, in particular problem/solution coevolution and information use. However, these different perspectives have to-date been modelled separately, making holistic description of design activity difficult. This paper takes the first steps towards linking these disparate perspectives in a model of designing that synthesizes coevolution and information processing. How designers act has been shown to play an important role in the process of New Product Development (NPD) (See e.g. Badke-Schaub and Frankenberger, 2012). Modelling design activity in NPD is typically done in one of three ways: object-, subject- or process oriented. First, it can be modelled by focusing on the object of design: the product. Second, it can be modelled by describing the social interaction and knowledge exchange between actors. Third, design activity can be modelled by describing the steps and phases that entails a specific design activity (Bedny & Harris, 2005). In all aspects and stages of the NPD process, uncertainty plays a key role both within the project itself as well as in relation to the project environment (Huang, Liu & Ho, 2015). In order to resolve uncertainty, both individuals and teams need to engage in decision making. In the case of decision making in a team, there is also greater scope for uncertainty, since personality and cognitive style influence decision making (Dewberry, Januchich & Narendran, 2013) and every person has a different perception of uncertainty. This difference can for example lead to a lack of agreement on the best solution. In NPD projects information is used to minimize the uncertainties inherent to innovation (Stockström & Herstatt, 2008; Huang, Liu & Ho, 2015), however, it is important to accept that there are uncertainties that can not be minimized and are inherent to the project itself (Ullman 2009). Thus, in NPD, the designer's activity is impacted by a wide range of variables. First, uncertainty is significant both inside and outside the project (as in the market for example), and is perceived and acted upon by the designer. Uncertainty perception can be connected to personal characteristics and cultural background, as well as experience and domain specific knowledge. The designer may perceive uncertainty arising from the design of the artefact, from the market, from consumer use, from prototyping, and others. Second, the designer's perceived uncertainty is the motivation to start a process of collecting, exchanging, and integrating knowledge. This has been formalised in Information-Processing Theory and more generally described by authors such as Aurisicchio et al. (2013) who describe design as an information transformation process. Here the aim of the activity is to reduce the perceived uncertainty through identifying and integrating external information and knowledge within the design team. For example, when perceiving uncertainty the designer might seek new information online, process this information, and share with their team in order to assess e.g. opinion, after that they process this knowledge and information together with their interpretation, giving a context to it and finally analysing if the new knowledge is helpful. Third, the designer's perceived uncertainty might also be the motivation to start a process of synthesizing information and ideas into new design propositions through the process of simulation. That is, design work is characterised by an iterative process between problem and solution space, also termed design coevolution (Poon and Maher, 1997; Dorst and Cross, 2001). This describes how problem and solution coevolve over time and have a mutual effect on one another, helping the designer to resolve high levels of uncertainty (Christensen & Ball, 2013). Thus in resolving NPD projects two fundamental processes are the manipulation and evolution of the problem and solution spaces (Christensen & Ball, 2013), and the transformation of information (Aurisicchio et al., 2013). However, prior research has traditionally modelled these perspectives separately; making holistic description of designer activity difficult. Thus, the aim of this paper is to propose a model that links design coevolution and information processing via uncertainty perception. This brings us to the following question: How are coevolution, information processing, and perception of uncertainty connected? The paper is structured in the following way. First, it presents the definitions and literature review of Uncertainty Perception, Information Processing, and Coevolution highlighting connections between them. The proposed model is then presented and explained. The paper closes with conclusions, limitations, and suggestions for further studies, including testing of the model itself.

An adaptive large neighborhood search heuristic for the Electric Vehicle Scheduling Problem

This paper addresses the Electric Vehicle Scheduling Problem (E-VSP), in which a set of timetabled bus trips, each starting from and ending at specific locations and at specific times, should be carried out by a set of electric buses or vehicles based at a number of depots with limited driving ranges. The electric vehicles are allowed to be recharged fully or partially at any of the given recharging stations. The objective is to firstly minimize the number of vehicles needed to cover all the timetabled trips, and secondly to minimize the total traveling distance, which is equivalent to minimizing the total deadheading distance. A mixed integer programming formulation as well as an Adaptive Large Neighborhood Search (ALNS) heuristic for the E-VSP are presented. ALNS is tested on newly generated E-VSP benchmark instances. Result shows that the proposed heuristic can provide good solutions to large E-VSP instances and optimal or near-optimal solutions to small E-VSP instances.

Analysis of national Jatropha biodiesel programme in Senegal

Growing Jatropha curcas for energy applications has been established through several initiatives in Senegal. The government of Senegal launched the National Jatropha Programme (NJP) in 2006 with the goal of planting 321,000 ha of Jatropha curcas, with an average of 1000 hectares (ha) in each rural locality. This paper reviews existing policies with relevance to Jatropha curcas L production in Senegal. It assesses the NJP implementation, identifies potential gaps and provides recommendations with regards to planning, institutional management, regulation, and implementation. The potential of Jatropha and other biodiesel crop options, based on findings from an agro-environmental mapping exercise have been shown. Findings show that prior policies in agricultural and energy sectors had been instrumental in developing the NJP. It highlights significant challenges in the value chain, the implementation of NJP and on the importance of using empirical assessment of evidence to inform on the biodiesel crop type compared to a focus on only one crop, Jatropha. Agro-environmental mapping was identified as useful technique prior to biodiesel cultivation. The work reported here indicates Jatropha having the largest suitability of land areas equating to almost thirty times (30) the original estimations in the NJP followed by Pongamia and sunflower with 6,796,000 ha and 5,298,900 ha respectively. Recommendations are provided suggesting, scientifically sound analysis from agro-environmental mapping to inform on the suitability of areas for Jatropha cultivation and on environmentally, socially and culturally sensitive areas. Policy options have been suggested for environmentally benigned sustained biodiesel activities in Senegal.

Analysis of regulation and economic incentives of the hybrid CSP HYSOL
The European HYSOL project, developed over the last three years in the solar thermal plant Manchasol (Ciudad Real, Spain), has been successfully completed, demonstrating that hybridisation of CSP with other energy sources (renewable and fossil) ensures power supply to the power grid in a stable and firm way, regardless the weather conditions.

Analysis of visual representation techniques for product configuration systems in industrial companies
In recent years, there has been an increasing demand for customized products. Product configuration systems (PCS) are introduced as one of the most successful systems of artificial intelligent for providing customized products. One of the main challenges in PCSs projects are described in relation with knowledge representations and communications with domain experts. The results presented in the paper are therefore aimed to provide insight into the impact from using visual knowledge representations techniques in PCSs projects. The findings indicate that use of visual knowledge representations techniques in PCSs projects will result in improved quality of maintenance and development support for the knowledge base and improved quality of the communication with domain experts.

An analysis of vendor innovation capability in the contract electronics manufacturing industry

Limited academic research has been given to analysing the innovation capabilities of vendors in outsourcing contracts. This paper seeks to address this gap in the literature by enhancing our understanding of how the innovation capability of vendors is deployed to win, run and renew outsourcing contracts with their customers. Employing the resource-based view as a theoretical basis and undertaking in-depth case study analysis of three vendors in the electronic manufacturing services industry, the research shows that to achieve the outsourcing objectives of winning, running and renewing the contract, vendors can use different configurations of the competitive priorities of cost, quality, delivery and flexibility. The research aggregates the capabilities that influence the innovative capability of a vendor into the innovation-related capabilities (IRCs) of design, new product introduction and manufacturing. Three strategies are identified for vendors on how to deploy these IRCs, and a number of propositions are developed to indicate the suitability of the three deployment strategies for different operational contexts.

An applied optimization based method for line planning to minimize travel time

The line planning problem in rail is to select a number of lines from a potential pool which provides sufficient passenger capacity and meets operational requirements, with some objective measure of solution line quality. We model the problem of minimizing the average passenger system time, including frequency-dependent estimates for switching between lines, working with the Danish rail operator DSB and data for Copenhagen commuters. We present a multi-commodity flow formulation for the problem of freely routing passengers, coupled to discrete line-frequency decisions selecting lines from a predefined pool. We show results directly applying this model to a Copenhagen commuter rail problem.

A new approach to the Container Positioning Problem

In this paper the Container Positioning Problem is revisited. This problem arises at busy container terminals and requires one to minimize the use of block cranes in handling the containers that must wait at the terminal until their next means of transportation. We propose a new Mixed Integer Programming model that not only improves on earlier attempts at this problem, but also better reflects reality. In particular, the proposed model adopts a preference to reshuffle containers in line with a just-in-time concept, as it is assumed that data is more accurate the closer to a container’s scheduled departure the time is. Other important improvements include reduction in the model size, and the ability of the model to consider containers initially at the terminal. In addition, we describe several classes of valid inequalities for this new formulation and present a rolling horizon based heuristic for solving larger instances of the problem. We show that this new formulation drastically outperforms previous attempts at the problem through a direct comparison on instances available in the literature. Furthermore, we also show that the rolling horizon based heuristic can further reduce the solution time on the larger of these instances as well as find acceptable solutions to much bigger, artificially generated, instances.

An integrated micro-macro approach to robust railway timetabling

With the increasing demand for railway transportation infrastructure managers need improved automatic timetabling tools that provide feasible timetables with enhanced performance in short computation times. This paper proposes a hierarchical framework for timetable design which combines a microscopic and a macroscopic model of the network. The framework performs an iterative adjustment of train running and minimum headway times until a feasible and stable timetable has been generated at the microscopic level. The macroscopic model optimizes a trade-off between minimal travel times and maximal robustness using an Integer Linear Programming formulation which includes a measure for delay recovery computed by an integrated delay propagation model in a Monte Carlo setting. The application to an area of the Dutch railway network shows the ability of the approach to automatically compute a feasible, stable and robust timetable. Practitioners can use this approach both for effective timetabling and post-evaluation of existing timetables.

An Introduction to Experimental Design Research
Design research brings together influences from the whole gamut of social, psychological, and more technical sciences to create a tradition of empirical study stretching back over 50 years (Horvath 2004; Cross 2007). A growing part of this empirical tradition is experimental, which has gained in importance as the field has matured. As in other evolving disciplines, e.g. behavioural psychology, this maturation brings with it ever-greater scientific and methodological demands (Reiser 1939; Dorst 2008). In particular, the experimental paradigm holds distinct and significant challenges for the modern design researcher. Thus, this book brings together leading researchers from across design research in order to provide the reader with a foundation in experimental design research; an appreciation of possible experimental perspectives; and insight into how experiments can be used to build robust and significant scientific knowledge. This chapter sets the stage for these discussions by introducing experimental design research, outlining the various types of experimental approach, and explaining the role of this book in the wider methodological context.

Application of Lean Manufacturing in Hospitals-the Need to Consider Maturity, Complexity, and the Value Concept
Lean is widely applied in hospitals, but the impact tends to be limited. This paper investigates three possible explanations: 1) maturity, 2) complexity, and 3) the value concept and analyses the bearing of these in a case study of lean application in a large Danish university hospital. The results indicate that lean tends to be applied in secondary and support functions with a logistic character and therefore has had a limited impact on the overall healthcare performance. The case study shows that there are constraints related to low lean maturity, the complexity of processes and operations as well as differences in value perceptions among the different professions (e.g., doctors, nurses, and managers) within the hospital. The conclusion is that lean is useful for hospitals, but the lean concept as well as its implementation methods need to be fitted to the organizational complexity and diverging values in hospitals in order to bring about a larger impact. It is therefore necessary to develop new models for the lean concept as well as the implementation of lean adapted to the particular context of hospitals with a stronger focus on patient experiences and on coordination of social relations.
The calculation of emissions from the use of pesticides is a critical issue in LCA studies of agrifood products and only occasionally discussed in details in literature studies. The objective of this study is to assess the results of the application of PestLCI 2.0 model to the production of maize in Northern Italy using site-specific soil and climate data, which were added for this purpose in PestLCI database. In
Approaches to formalization of the informal waste sector into municipal solid waste management systems in low- and middle-income countries: Review of barriers and success factors

The Municipal Solid Waste Management (MSWM) sector represents a major challenge for low-and middle-income countries due to significant environmental and socioeconomic issues involving rapid urbanization, their MSWM systems, and the existence of the informal waste sector. Recognizing its role, several countries have implemented various formalization measures, aiming to address the social problems linked to this sector. However, regardless of these initiatives, not all attempts at formalization have proved successful due to the existence of barriers preventing their implementation in the long term. Along with this, there is a frequent lack of knowledge or understanding regarding these barriers and the kind of measures that may enable formalization, thereby attaining a win-win situation for all the stakeholders involved. In this context, policy- and decision-makers in the public and private sectors are frequently confronted with the dilemma of finding workable approaches to formalization, adjusted to their particular MSWM contexts. Building on the review of frequently implemented approaches to formalization, including an analysis of the barriers to and enabling measures for formalization, this paper aims to address this gap by explaining to policy- and decision-makers, and to waste managers in the private sector, certain dynamics that can be observed and that should be taken into account when designing formalization strategies that are adapted to their particular socioeconomic and political-institutional context. This includes possible links between formalization approaches and barriers, the kinds of barriers that need to be removed, and enabling measures leading to successful formalization in the long term. This paper involved a literature review of common approaches to formalization, which were classified into three categories: (1) informal waste workers organized in associations or cooperatives; (2) organized in CBOs or MSEs; and (3) contracted as individual workers by the formal waste sector. This was followed by the identification and subsequent classification of measures for removing common barriers to formalization into five categories: policy/legal, institutional/organizational, technical, social, and economic/financial. The approaches to formalization, as well as the barrier categories, were validated through the assessment of twenty case studies of formalization. Building on the assessment, the paper discussed possible links between formalization approaches and barriers, the 'persistent' challenges that represent barriers to formalization, as well as key enabling factors improving the likelihood of successful formalization. Regardless of the type of approach adopted to formalization, the review identifies measures to remove barriers in all five categories, with a stronger link between the approaches 1 and 2 and the existence of measures in the policy, institutional, and financial categories. Regarding persistent barriers, the review identified ones arising from the absence of measures to address a particular issue before formalization or due to specific country- or sector-related conditions, and their interaction with the MSWM context. 75% of the case studies had persistent barriers in respect of policy/legal issues, 50% of institutional/organizational, 45% of financial/economic, and 40%, and 35% of social and technical issues respectively. This paper concludes that independently of the formalization approach, the lack of interventions or measures in any of the five categories of barriers may lead formalization initiatives to fail, as unaddressed barriers become 'persistent' after formalization is implemented. Furthermore, 'persistent barriers' may also appear due to unfavorable country-specific conditions. The success of a formalization initiative does not depend on a specific approach, but most likely on the inclusion of country-appropriate measures at the policy, economic and institutional levels. The empowerment of informal waste-workers is again confirmed as a further key success factor for their formalization.

A Prediction-based Smart Meter Data Generator

With the prevalence of cloud computing and Internet of Things (IoT), smart meters have become one of the main components of smart city strategy. Smart meters generate large amounts of fine-grained data that is used to provide useful information to consumers and utility companies for decision-making. Now-a-days, smart meter analytics systems consist of analytical algorithms that process massive amounts of data. These analytics algorithms require ample amounts of realistic data for testing and verification purposes. However, it is usually difficult to obtain adequate amounts of realistic data, mainly due to privacy issues. This paper proposes a smart meter data generator that can generate realistic energy consumption data by making use of a small real-world dataset as seed. The generator generates data using a prediction-based method that depends on historical energy consumption patterns along with Gaussian white noise. In this paper, we comprehensively evaluate the efficiency and effectiveness of the proposed method based on a real-world energy data set.

A proposal to measure absolute environmental sustainability in lifecycle assessment

Environmental monitoring indicates that progress towards the goal of environmental sustainability in many cases is slow, non-existing or negative. Indicators that use environmental carrying capacity references to evaluate whether anthropogenic systems are, or will potentially be, environmentally sustainable are therefore increasingly important. Such absolute indicators exist, but suffer from shortcomings such as incomplete coverage of environmental issues, varying data quality and varying or insufficient spatial resolution. The purpose of this article is to demonstrate that life cycle assessment (LCA) can potentially reduce or eliminate these shortcomings. We developed a generic mathematical framework for the use of carrying capacity as environmental sustainability reference in spatially resolved life cycle impact assessment models and applied this framework to the LCA impact category terrestrial acidification. In this application carrying capacity was expressed as acid deposition (eq. mol H+ ha−1 year−1) and derived from two complementary pH related thresholds. A geochemical steady-state model was used to calculate a carrying capacity corresponding to these thresholds for 99,515 spatial units worldwide. Carrying capacities were coupled with deposition factors from a global deposition model to calculate characterisation factors (CF), which expresses space integrated occupation of carrying capacity (ha year) per kg emission. Principles for calculating the entitlement to carrying capacity of anthropogenic systems were then outlined, and the logic of considering a studied system environmentally sustainable if its indicator score (carrying capacity occupation) does not exceed its carrying capacity entitlement was demonstrated. The developed CFs and entitlement calculation principles were applied to a case study evaluating emission scenarios for personal residential electricity consumption supplied by production from 45 US coal fired electricity plant. Median values of derived CFs are 0.16–0.19 ha year kg−1 for common acidifying compounds. CFs are generally highest in Northern Europe, Canada and Alaska due to the low carrying capacity of soils in these regions. Differences in indicator scores of the case study emission scenarios are to a
larger extent driven by variations in pollution intensities of electricity plants than by spatial variations in CFs. None of the 45 emission scenarios could be considered environmentally sustainable when using the relative contribution to GDP or the grandfathering (proportionality to past emissions) valuation principles to calculating carrying capacity entitlements. It is argued that CFs containing carrying capacity references are complementary to existing CFs in supporting decisions aimed at simultaneously reducing environmental impacts efficiently and maintaining or achieving environmental sustainability. We have demonstrated that LCA indicators can be modified from being relative to being absolute indicators of environmental sustainability. Further research should focus on quantifying uncertainties related to choices in indicator design and on reducing uncertainties effectively. © 2015 Elsevier Ltd. All rights reserved.
A real options approach to analyse wind energy investments under different support schemes

A real options model is developed to evaluate wind energy investments in a realistic and easily applicable way. Considering optimal investment timing and sizing (capacity choice), the model introduces a capacity constraint as part of the optimisation. Several correlated uncertainty factors are combined into a single stochastic process, which allows for analytical (closed-form) solutions. The approach is well suited for quantitative policy analysis, such as the comparison of different support schemes. A case study for offshore wind in the Baltic Sea quantifies differences in investment incentives under feed-in tariffs, feed-in premiums and tradable green certificates. Investors under certificate schemes require up to 3% higher profit margins than under tariffs due to higher variance in profits. Feed-in tariffs may lead to 15% smaller project sizes. This trade-off between faster deployment of smaller projects and slower deployment of larger projects is neglected using traditional net present value approaches. In the analysis of such trade-off, previous real options studies did not consider a capacity constraint, which is here shown to decrease the significance of the effect. The impact on investment incentives also depends on correlations between the underlying stochastic factors. The results may help investors to make informed investment decisions and policy makers to strategically design renewable support and develop tailor-made incentive schemes.

Area of Concern: A new paradigm in life cycle assessment for the development of footprint metrics

As a class of environmental metrics, footprints have been poorly defined, have shared an unclear relationship to life cycle assessment (LCA), and the variety of approaches to quantification have sometimes resulted in confusing and contradictory messages in the marketplace. In response, a task force operating under the auspices of the UNEP/SETAC Life Cycle Initiative project on environmental life cycle impact assessment (LCIA) has been working to develop generic guidance for developers of footprint metrics. The purpose of this paper is to introduce a universal footprint definition and related terminology as well as to discuss modelling implications. The task force has worked from the perspective that footprints should be based on LCA methodology, underpinned by the same data systems and models as used in LCA. However, there are important differences in purpose and orientation relative to LCA impact category indicators. Footprints have a primary orientation toward society and nontechnical stakeholders. They are also typically of narrow scope, having the purpose of reporting only in relation to specific topics. In comparison, LCA has a primary orientation toward stakeholders interested in comprehensive evaluation of overall environmental performance and trade-offs among impact categories. These differences create tension between footprints, the existing LCIA framework based on the area of protection paradigm and the core LCA standards ISO14040/44. In parallel to area of protection, we introduce area of concern as the basis for a universal footprint definition. In the same way that LCA uses impact category indicators to assess impacts that follow a common cause-effect pathway toward areas of protection, footprint metrics address areas of concern. The critical difference is that areas of concern are defined by the interests of stakeholders in society rather than the LCA community. In addition, areas of concern are stand-alone and not necessarily part of a framework intended for comprehensive environmental performance assessment. The area of concern paradigm is needed to support the development of footprints in a way that fulfils their distinctly different purpose. It is also needed as a mechanism to extricate footprints from some of the provisions of ISO 14040/44 which are not considered relevant. Specific issues are identified in relation to double counting, aggregation and the selection of relevant indicators. The universal footprint definition and related terminology introduced in this paper create a foundation that will support the development of footprint metrics in parallel with LCA.
Argumentation and Reasoning in Design: An Empirical Analysis of the Effects of Verbal Reasoning on Idea Value in Group Idea Generation

Reasoning is argumentative and is at the core of design activity and thinking. Understanding the influence of reasoning on the value of ideas is key to support design practice. The paper aims to show the effect of verbal reasoning on the value of ideas. Protocol analyses of four industry cases doing idea generation shows that framing by certainty and deductive reasoning lead to useful incremental ideas while framing by uncertainty and abductive reasoning lead to radical ideas. The paper concludes that the way of framing ideas is indicative of how ideas add value to on-going design processes.

A Simple Synchro – Modal Decision Support Tool for the Piraeus Container Terminal

The concept of Synchro modality is effectively an evolution of a multimodal supply chain. It integrates different transport modes and gives shippers and logistics service providers the freedom to deploy different modes of transportation in the same chain and in a flexible way so as to gain the desired outcome according to their priorities in a certain trip. Time, costs and emissions are certainly the three most relevant parameters when talking about a multimodal transportation chain. In most cases the logistics provider has set priorities to conform with, and obviously above mentioned constrains influence each other in an adverse way. With the development of ICT technologies and systems installed on board and on shore and with a simple decision support system fed with input from tracking and tracing systems or traffic monitoring systems, one can easily and flexibly plan his transportation job and maintain his set priority while in parallel keeping the remaining two parameters in control. Down times for example could be eliminated and efficiency gains could be achieved with decreased environmental footprint.

The Port of Piraeus is the largest Greek seaport and one of the largest ports in the Mediterranean Sea basin. It exhibits an impressive container traffic growth rate over the last 4 years triggered by its partial privatization and a recently completed hinterland connection to the rail network, which associated the port with the South-Eastern European corridor e.g. the route Far Eastern ports–Piraeus–Prague.

The current paper will present an easy to use simple tool to continuously assess even during the transportation event all the alternative modes for a given destination in terms of time cost and emissions. An analytical fully parameterized model will be the basis for this tool which will be run for the chain Shanghai–Piraeus–Prague. The overall scenario is as follows: A container ship is arriving from China to the Piraeus Container Terminal. One of its containers is destined to an inland Enterprise in Prague. The most common way for transportation to Prague is rail, but also truck could be an alternative solution and of course a combination of a Short Sea Shipping part to Thessaloniki and then truck or train to Prague. Emphasis in the calculations will be given to emissions for all the modes and relations will be shown with time and cost.
The tool developed is based on the case study above, being however open architecture software it can be expanded and applied to other ports and routes. The final outcome will be an easy and user friendly tool with the possibility to alter different input parameters and receive quickly a useful decision support system for the shipper or the logistics providers. Finally, there are two loops foreseen for the runs of the program. The required input parameters at each stage are either directly fed to the program if available (e.g. vessels ETA and position through GPS, VTS, ETC) or calculated if this is not the case.

Assessing environmental performance of humidification technology used in supply of fresh fruit and vegetables

Distributions chains in Europe of most fresh fruit and vegetables follow a pattern where fruit or vegetables produced in southern European countries are typically transported to countries in the central or northern parts of Europe. The relatively complex supply and distribution chain with many actors involved (from farmers, through wholesalers, to retailers) highlights the need for minimizing food loss in the post-harvest to optimize the overall environmental performance of agricultural systems in Europe.

Humidification is an emerging technology that can potentially contribute to minimize post-harvest losses of fruit and vegetables. Humidifiers release a fine mist thereby reducing the difference in water vapour pressure at the surface of the fruit or vegetable and in the air, preventing dry-out of fruits and deterioration. In addition, humidification provides cooling as a result of the evaporation of the droplets into the unsaturated air, without exchange with the environment (adiabatic cooling effect). The overall environmental performance of the humidification technology is expected to be determined by the trade-offs between lower environmental impacts stemming mainly from a reduction in loss and associated agricultural efforts and increased impacts mainly due to the need for new equipment and increased water use.

We assessed environmental performance of humidification technology in the European context. Lettuce produced in Italy and transported to Denmark was chosen as a case study, and sensitivity scenarios considered strawberries, flat peaches, asparagus, and table grapes. The results show that the technology has the potential to reduce life cycle environmental impacts, provided that it allows reducing food loss in the post-harvest. When compared to the conventional supply chain of lettuce without humidification, the impact scores are reduced on average by 2.6, 6.0 and 7.4% when the total losses of the supply chain are decreased by 2, 5 and 6%, respectively (corresponding to low, medium and high efficiency of the technology). This is true for all impact categories, except resource depletion which is driven by the humidifier production and disposal stages rather than agriculture. Thus, depending on the performance of humidifying units, humidification may have the potential to reduce environmental impacts stemming from supply of fresh fruit and vegetables in Europe.

Assessing the cost saving potential of shared product architectures
This article presents a method for calculating cost savings of shared architectures in industrial companies called Architecture Mapping and Evaluation. The main contribution is an operational method to evaluate the cost potential and evaluate the number of product architectures in an industrial company. Experiences from the case company show it is possible to reduce the number of architectures with 60% which leads to significant reduction in direct material and labor costs. This can be achieved without compromising the market offerings of products. Experiences from the case study indicate cost reductions between 0.5% and 2% of turnover. The main implication is that the method provides a quantitative basis for the discussion on whether or not to implement shared product architectures. This means a more fact-based approach is introduced.

Assessing the influence of groundwater and land surface scheme in the modelling of land surface-atmosphere feedbacks over the FIFE area in Kansas, USA

The land surface-atmosphere interaction is described differently in large scale surface schemes of regional climate models and small scale spatially distributed hydrological models. In particular, the hydrological models include the influence of shallow groundwater on evapotranspiration during dry periods where soils are depleted and groundwater is the only water supply. These mechanisms are analysed by combining a distributed hydrological model (MIKE SHE) and a regional climate model (HIRHAM) and comparing simulation results to the FIFE area observation data in Kansas, USA. The numerical experiments include five simulations. First MIKE SHE is forced by observed climate data in two versions i) with groundwater at a fixed uniform depth, and ii) with a dynamical groundwater component simulating shallow groundwater conditions in river valleys. iii) In a third simulation MIKE SHE is forced by HIRHAM simulated precipitation. The last two simulations include iv) a standard HIRHAM simulation, and v) a fully coupled HIRHAM-MIKE SHE simulation locally replacing the land surface scheme by MIKE SHE for the FIFE area, while HIRHAM in standard configuration is used for the remaining model area. The results show a clear correlation between depth to the groundwater and evapotranspiration with a distinct groundwater depth threshold at 0.5-3 m. During the dry summer period the two MIKE SHE simulations using distributed groundwater reproduced evapotranspiration better than MIKE SHE with unsaturated flow alone and the HIRHAM simulations. This indicates that including dynamic groundwater in a fully coupled climate-hydrological model may improve evapotranspiration fluxes from areas with shallow groundwater tables.
Assessment of Metal Toxicity in Marine Ecosystems: Comparative Toxicity Potentials for Nine Cationic Metals in Coastal Seawater

This study is a first attempt to develop globally applicable and spatially differentiated marine Comparative Toxicity Potentials (CTPs) or ecotoxicity characterization factors for metals in coastal seawater for use in Life Cycle Assessment. The toxicity potentials are based exclusively on marine ecotoxicity data and take account of metal speciation and bioavailability. CTPs were developed for nine cationic metals (Cd, Cr(III), Co, Cu(II), Fe(III), Mn, Ni, Pb and Zn) in 64 Large Marine Ecosystems (LMEs) covering all coastal waters in the world. The results showed that the CTP of a specific metal varies 3-4 orders of magnitude across LMEs, largely due to different seawater residence time. Therefore the highest toxicity potential for metals was found in the LMEs with the longest seawater residence times. Across metals, the highest CTPs were observed for Cd, Pb and Zn. At the concentration levels occurring in coastal seawaters, Fe acts not as a toxic agent but an essential nutrient and thus has CTPs of zero.

General information
A step-by-step plan to manage and measure adding value by FM/CREM.

Purpose
To present a new Value Adding Management model in order to support decision makers in identifying appropriate interventions to add value to the organisation, to manage its implementation, and to measure the output and outcomes.

Theory
The paper builds on value adding management theories and models including the triplet input-throughput-output, a distinction between output, outcome and added value, the Plan-Do-Act-Check cycle, change management and performance measurement. Design/methodology/approach Literature review and a cross-chapter analysis of a forthcoming book, where authors from different European countries present a state of the art of theory and research on 12 value parameters, how to manage and measure each value, and to discuss the costs and benefits of typical FM and CREM interventions to enhance satisfaction, image, culture, health and safety, productivity, adaptability, innovation, risk, cost, value of assets, sustainability and Corporate Social Responsibility.

Findings
The new Value Adding Management model follows the steps from the well-known Plan-Do-Check-Act cycle. The four steps are supported by various tools that were found in the literature or came to the fore in the state-of-the-art sections of the 12 value parameters. Furthermore an overview is presented of ways to measure the 12 value parameters and related Key Performance Indicators.

Originality/value
Much has been written about adding value by FM and CREM. This paper presents a new Value Adding Management model that opens the black box of input-throughput-output-outcome and which is supported by various management and measurement tools.

A systematic approach applied in design of a micro heat exchanger

The number of products benefiting from micro components in the market is increasing, and consequently, the demand for well-matched tools, equipment and systems with micro features is eventually increasing as well. During the design process of micro products, a number of issues appear which are inherent due to the down scaling or physical phenomena dominating in the micro range but negligible in the macro scale. In fact, some aspects in design for micro manufacturing are considerably different compared to the design procedure taken at the macro level. Identifying the differences between design considerations at micro compared to macro scale, and defining potential guidelines based on them, provides an opportunity to modify the conventional design methodologies towards becoming micro specific. In this paper, the need for a micro-oriented approach for designing micro products which has not been investigated hitherto is studied.

For this purpose, an additional step named “Rules To Consider” (RTC) is added to the conventional design methodologies. This step is constituted based on the feedbacks gained during analyzing the different iterations of the design. The knowledge obtained during the design process of a micro product can be added to the RTC unit, and this unit becomes enriched progressively in design process of similar micro products and supplemented to the conventional design methodologies to be served as a micro-oriented design methodology. In order to present the application of RTC unit, the design process of a micro heat exchanger is investigated. Manufacturability and functional performance are considered as evaluation criteria, and the lessons learned from each design iteration and evaluation are employed in the subsequent design proposals until an acceptable design is achieved. Thermal performance of the heat exchangers is evaluated using finite element (FE) simulation of the conjugate heat transfer. The design proposals are optimized in terms of geometrical dimensions, and a sensitivity analysis is conducted on the mass flow rate and heat generation power in the heat source. Finally, the designs with higher thermal performance and manufacturability are introduced. The result of the thermal analysis reveals the fact that the presence of the fins and modification of their dimensions as well as the constituent material for fabricating the micro heat exchanger do not significantly improve the thermal performance of the micro heat exchangers. This is an interesting outcome which can result in considerable reduction of the manufacturing costs by simplifying the geometrical design of the heat exchanger. The micro-specific design considerations which are extracted from the design process of the micro heat exchanger are added to the RTC unit and can be applied as guidelines in design process of any other micro heat exchanger. In other words, the current study can provide a useful guideline in design for manufacturing of micro products.

A three-level framework for performance-based railway timetabling

The performance of railway operations depends highly on the quality of the railway timetable. In particular for dense railway networks it can be challenging to obtain a stable robust conflict-free and energy-efficient timetable with acceptable infrastructure occupation and short journey times. This paper presents a performance-based railway timetabling framework integrating timetable construction and evaluation on three levels: microscopic, macroscopic, and a corridor fine-tuning level, where each performance indicator is optimized or evaluated at the appropriate level. A modular implementation of the three-level framework is presented and demonstrated on a case study on the Dutch railway network illustrating the feasibility of this approach to achieve the highest timetabling design level.

A Weighted K-AP Query Method for RSSI based Indoor Positioning

The paper studies the establishment of offline fingerprint library based on RSSI (Received Signal Strength Indication), and proposes WF-SKL algorithm by introducing the correlation between RSSIs. The correlations can be transformed as AP fingerprint sequence to build the offline fingerprint library. To eliminate the positioning error caused by instable RSSI value, WF-SKL can filter the noise AP via online AP selection, meanwhile it also reduces the computation load. WF-SKL utilizes LCS algorithm to find out the measurement between the nearest neighbors, and it proposes K-AP (P,Q) nearest neighbor queries between two sets based on Map-Reduce framework. The algorithm can find out K (P,Q) nearest positions and weighted them for re-positioning to accelerate the matching speed between online data and offline data, and also improve the efficiency of positioning. According to a large scale positioning experiments, WF-SKL algorithm proves its high accuracy and positioning speed comparing with KNN indoor positioning.

Back to basics - the school lunch

Purpose

The effort to develop social life cycle assessment (Social LCA) along the same principles and procedural steps as LCA has met serious challenges when characterizing social impacts as originating from product life cycles and attributing them to unit processes. This article puts the resulting life cycle CSR and its focus on the production phase on hold. It suggests a research design to support consumers in choosing between, e.g. alternative school lunch scenarios, according to their subjective social and cultural values.

Methods

Inspired by Reverse LCA, the focus of life cycle CSR on the production phase is shifted to the consumer need. Reverse LCA claims that starting with the need will point to alternative innovative systems of products and services to fulfil that need. The assessment to identify the system with the minimal environmental impact can then be established in reverse. The concept of foodscape captures the school lunch as a specific configuration of food products, social practices and values. The concept of human well-being defined by Amartya Sen and elaborated by Martha C. Nussbaum helps to characterize the needs involved in the school lunch. The assessment is performed as action research by the community of stakeholders involved and using an interactive scenario analysis.

Results and discussion

As a first step, the outline research design acknowledges that schools embody a distinct and articulate stakeholder community advocating multidimensional needs, the fulfillment of which is continuously evaluated for prioritization and optimization. Second, three preliminary school lunch scenarios are identified. The concept of foodscape is introduced to clarify and characterize dimensions, assumptions and fundamental choices for each scenario. As a third step, stakeholders evaluate and profile each scenario in terms of valuable functionings for human well-being. Furthermore, stakeholders review documentation on environmental and social impacts throughout the earlier stages of the product life cycles involved. The targeted outcome of stakeholders’ negotiation is a decision on a particular configuration, for which an action plan detailing the pathway to the desired school lunch scenario is adopted.

Conclusions

The introduction of the concepts of foodscape and human well-being supports the argument that social LCA needs a strong foundation in social theory for the specific domain to be assessed and for the overall conceptualization of social impacts. Dialogues with social scientists are needed, especially with those who apply a life cycle perspective.

Band gap tuning of amorphous Al oxides by Zr alloying
The optical band gap and electronic structure of amorphous Al-Zr mixed oxides, with Zr content ranging from 4.8 to 21.9%, were determined using vacuum ultraviolet (VUV) and X-ray absorption spectroscopy (XAS). Thelight scattering by the nano-porous structure of alumina at low wavelengths was estimated based on the Mie scattering theory. The dependence of the optical band gap of the Al-Zr mixed oxides on Zr content deviates from linearity and decreases from 7.3 eV for pure anodized Al2O3 to 6.45 eV for Al-Zr mixed oxide with Zr content of 21.9%. With increasing Zr content, the conduction band minimum changes non-linearly as well. Fitting of the energy band gap values resulted in a bowing parameter of 2 eV. The band gap bowing of themixed oxides is assigned to the presence of the Zr d-electron states localized below the conduction band minimum of anodized Al2O3.

Being green on sulphur: Targets, measures and side-effects

Green House Gas (GHG) emissions are not the only emissions of concern to the international transport community. SOx emissions are non-GHG emissions that are caused by the presence of sulphur in the fuel. As the maximum percentage of sulphur in automotive and aviation fuels is strictly regulated in most countries around the world, much of the attention in recent years has focused on maritime transport. The attention mainly stems from the fact that in marine fuels the percentage of sulphur can be very high: it can be as high as 4.5 % in Heavy Fuel Oil (HFO), which is the fuel typically used in all deep-sea trades. Even though the amounts of SOx produced by ships are substantially lower than CO2, SOx emissions are highly undesirable as they cause acid rain and undesirable health effects in humans and animals. To mitigate these adverse environmental effects, the international shipping community has taken substantial policy measures. With the introduction of new limits for the content of sulphur in marine fuels in Northern European and North American sea areas, short-sea companies operating in these areas will face substantial additional cost. As of 1/1/2015, international regulations stipulate, among other things, a 0.1% limit in the sulphur content of marine fuels, or equivalent measures limiting the percent of SOx emissions to the same amount. As low-sulphur fuel is substantially more expensive than HFO, there is little or no room within these companies current margins to absorb such additional cost, and thus significant price increases must be expected. Unlike its deep-sea counterpart, in short-sea shipping such a freight rate increase may induce shippers to use landbased alternatives (mainly road). A reverse shift of cargo would go against the EU policy to shift traffic from land to sea to reduce congestion, and might ultimately (under certain circumstances) increase the overall level of CO2 emissions along the entire supply chain. The purpose of this chapter is to investigate the potential effect of sulphur regulations on the share of cargo transported by the waterborne mode vis-à-vis land-based alternatives.

**Betydningen af sociale normer for distraktion under bilkørsel**
En amerikansk undersøgelse viser, at sociale normer har betydning for unges involvering i distraherende aktivitet. Interventioner, der støtter forældre i at være gode rollemodeller og bidrager til at korriger misforståelser angående omfanget af distraherende aktivitet blandt forældre og jævnaldrende kammerater, er derfor yderst relevante.

**Bio-based chemicals - green, but also sustainable?**
For almost two decades, the chemical industry has put great effort into developing bio-chemicals, among others to fight global warming caused by greenhouse gas emissions, one of the biggest threats that are faced by our society today. To facilitate a growing and versatile bio-based chemical production, the US Department of Energy proposed in 2004 a list of 12 building block chemicals which can either be converged through biological or chemical conversions. Moving toward more bio-based chemicals, the chemical industry does not only claim to reduce climate change impacts, but also that they are increasing overall sustainability in chemical production. Whether such claims are justifiable is unclear. When sustainability of bio-based polymer production is assessed, various environmental trade-offs occur that need to be considered. It is not enough to claim that a bio-chemical is sustainable by exclusively looking at reduced
global warming impacts related to avoiding oil refining and related greenhouse gas emissions. However, there is big variation of which impacts are assessed and which life cycle stages are included between existing published studies focusing on assessing environmental sustainability of bio-based polymers.

**Biodiesel from microalgae – greenhouse gas emissions and energy balance**
The current use of fossil fuels is problematic for both environmental and economic reasons and biofuels are regarded as a potential solution to current energy issues. This study analyzes the energy balances and greenhouse gas emissions of 24 different technology scenarios for the production of algal biodiesel from Nannochloropsis cultivated at industrial scale in photobioreactors in Denmark. Both consolidated and pioneering technologies are analyzed focusing on strengths and weaknesses which influence the performance. Based on literature data, energy balance and greenhouse gas emissions are determined in a comparative ‘well-to-tank’ Life Cycle Assessment against fossil diesel. Use of by-products from biodiesel production such as glycerol obtained from transesterification and anaerobic digestion of residual biomass are included. Different technologies and methods are considered in cultivation stage (freshwater vs. wastewater; synthetic CO2 vs. waste CO2), harvesting stage (flocculation vs. centrifugation) and oil extraction stage (hexane extraction vs. supercritical CO2 extraction). The choices affecting environmental performance of the scenarios are evaluated. Results show that algal biodiesel produced through current conventional technologies has higher energy demand and greenhouse gas emissions than fossil diesel. However, greenhouse gas emissions of algal biodiesel can be significantly reduced through the use of ‘waste’ flows (nutrients and CO2) but there are still technical difficulties with both microalgae cultivation in wastewater as well as transportation and injection of waste CO2. In any way, a positive energy balance is still far from being achieved. Considerable improvements must be made to develop an environmentally beneficial microalgae biodiesel production on an industrial scale. In particular, different aspects of cultivation need to be enhanced, such as the use of wastewater and CO2-rich flue gas from industrial power plants.

**Biodiversity and ecosystem services in life cycle impact assessment – Inventory objects or impact categories?**
Biodiversity and ecosystem services are both sensitive to the way we utilize and manage ecosystems and landscapes, but they are not unambiguously linked. It is argued that in Life Cycle Impact Assessment (LCIA) the Area Of Protection (AoP) ‘natural environment’ should be divided into two AoP’s, namely ‘biodiversity’ and ‘ecosystem services’. The AoP biodiversity has more emphasis on intrinsic (existence) values than on utilitarian, functional value perceptions that are covered by the AoP ecosystem services. Ecosystem services can in some aspects be substituted or restored, whereas certain biodiversity losses (e.g. loss of old-growth forest or extinction of a species) are irreversible and thus require a precautionary, conservationist approach. Further, it is suggested that global environmental change scenarios are used in LCIA in order to assess future pressures and potential damages to biodiversity and ecosystem service supplies as a basis for calculating the contribution of a product life cycle to the overall environmental damage.
Biomass Residues from Agriculture and Potential Contribution towards Modern Energy Supply in West Africa

Access to modern energy services especially in developing countries is an urgent issue. Globally, 1.3 billion people do not have access to modern energy and the services associated with it. Sub-Saharan Africa is one of the regions that have profound lack of modern energy access. The objective of this paper is to understand the role that residues obtained from agricultural practices could be utilised in providing electricity for use in West African countries. Selected countries include: Ghana, Nigeria, Senegal and Togo. The study utilized methods developed by Mendu et. al. 2012, Mabeeet. al. 2010, Ackom et.al., 2013, to estimate electricity production from agricultural residues in the selected countries. This study considered competing utilization of residues for animal fodder, bedding and nutrient recycling in the region. Findings show bioelectricity from residues could supply $0.6 \times 10^6 - 1.5 \times 10^7$ MWh (Ghana), $4.5 \times 10^6 - 13 \times 10^6$ MWh (Nigeria), $0.5 \times 10^6 - 1.2 \times 10^7$ MWh (Senegal) and $0.2 \times 10^6 - 1.3 \times 10^6$ MWh (Togo). This could help bring increased electrification from a renewable energy source to the countries especially in the farming communities where the...
residue abounds thus ensuring good prospect for improved quality of life, poverty alleviation and sustainable development.

Bosætningsmønstre i Storkøbenhavn – en model for boliglokalisering og bilejerskab
Viden om, hvordan folk vælger at bosætte sig, er et centralt emne inden for byforskning, og over de seneste år er det blevet muligt at lave simultan-analyser af, hvordan lokaliseringssafærd påvirker og påvirkes af forskellige politiktiltag og infrastrukturprojekter, samt hvordan lokaliseringsafæfærd hænger sammen med udviklingen af byer og urbane områder. Det kan således lade sig gøre at kigge på, hvordan disse forhold påvirker hinanden indbyrdes.

Bounded rational choice behaviour: applications in transport
Even though the theory of rational behaviour has been challenged for almost 100 years, the dominant approach within the field of transport has been based upon the assumptions of neoclassical economics that we live in a world of rational decision makers who always have perfect knowledge and aim to maximise some subjective measure. Where other fields, for example within the social sciences and psychology, have made serious efforts to explore alternative models derived from principles of bounded rationality, this direction has begun to take speed within transport applications only recently. Bounded rational choice behaviour focuses on how the latter approach can be seriously taken into account within
transport applications. As the editors discuss in the introduction, a true optimal choice can only be made if an individual has full and perfect information of all relevant attributes in his/her choice set. An individual is said to demonstrate bounded rational behaviour if he/she does not systematically consider all attributes deemed relevant for the decision problem at hand, does not consider all choice options and/or does not choose the best choice alternative. Such simplified representation and limited processing may occur due to time constraints, low involvement in the decision at hand, relying on habits or the task requiring too high a mental effort.

Business cases for product configuration systems
In the recent years, product configuration systems (PCSs) have received greater attention from industries providing customized products as a response to increased demand to fulfil diverse customers’ needs for customized products. Before developing a PCS, a well-established business case has to be made in order to secure the success and delivery of the project as it will increase the commitment from the business side. This paper presents a framework for supporting the development of business cases for PCSs and discusses the experiences from multiple case studies benefiting from the suggested framework.

Business process management and IT management: The missing integration
The importance of business processes and the centrality of IT to contemporary organizations’ performance calls for a specific focus on business process management and IT management. Despite the wide scope of business process management covering both business and IT domains, and the profound impact of IT on process innovations, the association between business process management and IT management is under-explored. Drawing on a literature
analysis of the capabilities of business process and IT governance frameworks and findings from a case study, we propose the need for horizontal integration between the two management functions to enable strategic and operational business - IT alignment. We further argue that the role of IT in an organization influences the direction of integration between the two functions and thus the choice of integration mechanisms. Using case study findings, we propose that IT as a business enabler respectively calls for sequential and reciprocal integrations at strategic and operational planning levels. Drawing on logical reasoning, we suggest that IT as a strategic driver necessitates reciprocal integration at both levels.

In this study we develop and test a calibration approach on a spatially distributed groundwater-surface water catchment model (MIKE SHE) coupled to a land surface model component with particular focus on the water and energy fluxes. The model is calibrated against time series of eddy flux measurements from three sites of different land surface type (agriculture, forest and meadow) and river discharge data from the 2500 km² Skjern River catchment in Denmark. The approach includes initial calibrations of three one-dimensional models representing the three land surface types using the flux measurements for calibration. This step provides initial values for the subsequent modelling and calibration at catchment scale. To test the validity of the approach, two additional catchment scale distributed simulations were performed with no calibration and only calibration of the one-dimensional models, respectively. In addition, a subsequent validation period was simulated. A mean energy closure imbalance of 20% was seen for the three sites. For the distributed simulations, the energy imbalance was accounted for by two energy balance closure hypotheses ascribing the error to either energy fluxes or net radiation. In general, the distributed calibration approach improved model results substantially compared to using default values (no calibration) or calibration of the one-dimensional models only. For the distributed model simulations, the assumption regarding the energy balance closure had a substantial impact on the parameter sensitivities and on the simulated discharge and energy balance. During calibration, the simulation with corrected energy fluxes showed better performance on discharge than the simulation with corrected net radiation whereas the reverse was true for the validation period. Regarding energy fluxes, the simulation with corrected net radiation was superior in both the calibration and validation period.
Campus Retrofitting (CARE) Methodology: A Way to Co-Create Future Learning Environments

The future learning environments are not based on standardized design solutions like lecture theatres for 100 persons or classrooms for 40 persons. As new technology and new ways of studying are being developed new demands are put on university environments. At the same time utilisation of resources in form of both teachers and university facilities is challenged by development of integration of learning, teaching and the spaces where it takes place. The challenges are shared among users and owners of campus, where retrofitting is needed too. This paper aims to describe Campus Retrofitting (CARE) methodology for user-centric and co-creative campus retrofitting processes. The campus development research in Nordic countries and co-creation in retrofitting processes are discussed. The campus retrofitting cases in different countries are described by emphasising especially the methods they used. Based on the analysis of the methods the framework for Campus retrofitting (CARE) methodology is presented and discussed. CARE-methodology is a tool to capture new logic to learning environment design. It has three key activities: co-creating, co-financing and co-evaluating. The integrated methodology and the formulation of the guiding principle of the CARE-way of sustainable retrofitting of university campuses opens up an agenda for investigating a new methodology for sustainable urban retrofitting in a Nordic context.

Carbono Cero América Latina - Una vía para la descarbonización neta de la economía regional para mediados de este siglo: Documento de visión

El objetivo del análisis presentado en este informe es identificar una vía para la descarbonización completa de la economía regional de América Latina y el Caribe (ALC) para mediados de este siglo. Esto se logra a través de una revisión de acciones sectoriales específicas dentro de un contexto tecnológico y económico previsible. El análisis se lleva a cabo en un momento de considerable discusión del problema del cambio climático a nivel mundial y después de una década de notable progreso socioeconómico a nivel regional. En el informe también se discuten las principales barreras que tienen que ser tratadas.

Causal Analysis of Railway Running Delays
Operating delays and network propagation are inherent characteristics of railway operations. These are traditionally reduced by provision of time supplements or “slack” in railway timetables and operating plans. Supplement allocation policies must trade off reliability in the service commitments against service transit times and railway asset productivity. Methods to investigate the quality of supplement time allocation are necessary to reduce the behavioral response and the waste of resources. This is a preliminary study that investigates train delay data from the year 2014 supplied by Rail Net Denmark (the Danish infrastructure manager). The statistical analysis of the data identifies the minimum running times and the scheduled running time supplements and investigates the evolution of train delays along given train paths. An improved allocation of time supplements would result in smaller overall aggregate timetable supplement, reduced transport travel times, and higher productive utilization of train rolling stock. The study results will lead eventually to both better allocation of time supplements in timetable structures, and identification of areas that should be a high priority for correction

Challenges in implementing a Planetary Boundaries based Life-Cycle Impact Assessment methodology
Impacts on the environment from human activities are now threatening to exceed thresholds for central Earth System processes, potentially moving the Earth System out of the Holocene state. To avoid such consequences, the concept of Planetary Boundaries was defined in 2009, and updated in 2015, for a number of processes which are essential for maintaining the Earth System in its present state. Life-Cycle Assessment was identified as a suitable tool for linking human activities to the Planetary Boundaries. However, to facilitate proper use of Life-Cycle Assessment for non-global environmental management, there is a need for linking non-global activities to impacts on a planetary level. In this study, challenges related to development and operationalization of a Planetary Boundary based Life-Cycle Impact Assessment method are identified and the feasibility of resolving the challenges and developing such methodology is discussed. The challenges are related to technical issues, i.e., modelling and including the Earth System processes and their control variables as impact categories in Life-Cycle Impact Assessment and to theoretical
considerations with respect to the interpretation and use of Life-Cycle Assessment results in accordance with the Planetary Boundary framework. The identified challenges require additional research before a Planetary Boundaries based Life-Cycle Impact Assessment method can be developed. Research on modelling the impacts on Earth System processes and on allocation of and entitlement to the 'safe operating space' appear to be most urgent for operationalizing a Planetary Boundaries based Life-Cycle Impact Assessment method. The results of a Planetary Boundaries based Life-Cycle Impact Assessment would be highly relevant and could provide novel insights on the environmental performance and sustainability of products and systems.

Challenges in LCA modelling of multiple loops for aluminium cans

Life Cycle Assessment (LCA) has traditionally played a key role in identifying the most efficient environmental design strategies and the best option for the end-of-life of products from an environmental point of view, within “one life cycle” approach. However, such an approach fails to capture one of the main features of circular product systems, i.e. the need to model multiple life cycles. There are some key methodological challenges that LCA has to face in order to exploit its potential in a circular economy framework, e.g. how to model the recycling of materials in multiple loops. We considered the case of closed-loop recycling for aluminium cans, where body and lid are different alloys, and discussed the abovementioned challenge. The Life Cycle Inventory (LCI) modelling of aluminium processes is traditionally based on a pure aluminium flow, therefore neglecting the presence of alloying elements. We included the effect of alloying elements on the LCA modelling of aluminium can recycling. First, we performed a mass balance of the main alloying elements (Mn, Fe, Si, Cu) in aluminium can recycling at increasing levels of recycling rate. The analysis distinguished between different aluminium packaging scrap sources (i.e. used beverage can and mixed aluminium packaging) to understand the limiting factors for multiple loop aluminium can recycling. Secondly, we performed a comparative LCA of aluminium can production and recycling in multiple loops considering the two aluminium packaging scrap sources. The results from the mass balance of the alloying elements showed that the limiting alloying element for continuous can-to-can recycling is Mn. Therefore we quantified the amount of Mn and primary Al that needs to be reintegrated in each scenario according to the recycling rate and used this information to perform an LCA of 30 recycling loops based on the actual alloy composition. From the comparative LCA the closed product loop option (i.e. using used beverage can scraps) turned out to have lower environmental impact than the open loop option (i.e. using mixed aluminium packaging scraps), at least with regard to climate change.

compositional aspects of the organization networks between information-dependent activities provide valuable insights to better manage complex engineering design processes. The proposed approach is applied to the development of a power plant, analyzing 79 process interfaces. The study reveals a relationship between the structure and composition of the process interfaces and reported interface problems. Implications of this approach include the integration of information about process and organization architectures, the systematic identification of key performance metrics associated with interface problems, and improved support for engineering managers by means of a better overview of information flows between activities.

Characterizing health impacts from indoor and outdoor exposure to fine particulates

Exposure to fine particulate matter (PM2.5) pollution is a major contributor to human disease burden as continuously shown in the Global Burden of Disease study series. Exposures to PM2.5 concentration outdoors and indoors contribute almost equally to this burden. Despite the importance, health impacts from exposure to PM2.5 are often excluded from life cycle impact assessment (LCIA) characterization profiles. This is in large part because of the lack of well-vetted harmonized guidance about how to consistently assess the exposures and impacts of indoor and outdoor emissions of PM2.5 and its precursors. We present a framework for calculating characterization factors for indoor and outdoor emissions of primary PM2.5 and secondary PM2.5 precursors, and a roadmap for further refining this modelling framework for operational use in LCIA. The framework was developed over the last three years by a task force convened under SETAC/UNEP auspices.

A recent SETAC Pellston Workshop® was convened to formalize guidance and methods for estimating the health impacts associated with PM2.5 exposure and to recommend PM2.5 characterization factors for application in life cycle assessment. The framework involves three stages—analyzing PM2.5 fate and exposure (including indoor and outdoor urban/rural environments), modeling exposure-response, and the integration of exposure-response and PM2.5 exposure reflecting population and location characteristics. Our exposure model is organized as a mass balance matrix that tracks the global fate of primary PM2.5 and secondary PM2.5 precursor emissions (both indoors and outdoors) as an embedded system of compartments including urban environments, rural environments, and indoor environments within urban and rural areas. After presenting the model structure, we will review initial results and will present geographic variability, discuss key uncertainties, and evaluate our model using results from other models and concentration measurements.

Circular economy: To be or not to be in a closed product loop? A Life Cycle Assessment of aluminium cans with inclusion of alloying elements

Packaging, representing the second largest source of aluminium scrap at global level, deserves a key role in the transition towards the circular economy. Life Cycle Assessment (LCA) of aluminium products has been typically based on one life cycle considering pure aluminium flows and neglecting the presence of alloying elements and impurities. However, this simplification undermines the potentials of using LCA to quantify the environmental performances of products in multiple loops, as required in the circular economy. This study aims to investigate the effects of including the actual alloy composition in the LCA of aluminium can production and recycling, in order to understand whether a can-to-can (i.e. closed product loop) recycling should be promoted or not. Mass balance of the main alloying elements (Mn, Si, Cu, Fe) was carried out at increasing levels of recycling rate, corresponding to a temporal interval of five years. Different aluminium packaging scrap sources were considered: mixed packaging aluminium scrap and used beverage can scrap. The outcomes of the mass balance were used to quantify the amount of Mn and primary Al that needs to be reintegrated in each scenario according to the recycling rate and this information was further used to perform an LCA of 30 loops of aluminium can production and recycling, based on the actual alloy composition. The LCA revealed that the closed product loop option (considering used beverage can scrap) has lower climate change impacts over the other recycling scenario using mixed Al packaging scrap. The main recommendation from an LCA methodological point of view is to include the idea of multiple co-functions in the functional unit definition. To further improve the environmental performances of the aluminium beverage can sector towards circular economy implementation the key actions are: to reduce the weight of the lid, to develop methods to separate the body and lid at the point of collection, and to investigate the potentials of a closed supply chain loop for aluminium cans in terms of combined environmental and economic value creation.

Climate change impacts on groundwater hydrology – where are the main uncertainties and can they be reduced?

This paper assesses how various sources of uncertainty propagate through the uncertainty cascade from emission scenarios through climate models and hydrological models to impacts with particular focus on groundwater aspects for a number of coordinated studies in Denmark. We find results similar to surface water studies showing that climate model uncertainty dominates for projections of climate change impacts on streamflow and groundwater heads. However, we find uncertainties related to geological conceptualisation and hydrological model discretisation to be dominating for projections of well field capture zones, while the climate model uncertainty here is of minor importance. The perspectives of reducing the uncertainties on climate change impact projections related to groundwater are discussed with particular focus on the potentials for reducing climate model biases through use of fully coupled climate-hydrology models.

Climate Change Risks – Methodological Framework and Case Study of Damages from Extreme Events in Cambodia

Climate change imposes some special risks on Least Developed Countries, and the chapter presents a methodological framework, which can be used to assess the impacts of key assumptions related to damage costs, risks and equity implications on current and future generations. The methodological framework is applied to a case study of severe storms in Cambodia based on statistical information on past storm events including information about buildings damaged and victims. Despite there is limited data available on the probability of severe storm events under climate change as well on the actual damage costs associated with the events in the case of Cambodia, we are using the past storm events as proxy data in a sensitivity analysis. It is here demonstrated how key assumptions on future climate change, income levels of victims, and income distribution over time, reflected in discount rates, affect damage estimates and thereby the economic recommendations for climate change adaptation decision making. The conclusion is that taken vulnerabilities and equity concerns into consideration in adaptation planning for Least Developed Countries really makes a strong case for allocating economic resources to the protection of these countries.

Closing the gap? Top-down versus bottom-up projections of China's regional energy use and CO₂ emissions
As the world's largest CO₂ emitter, China is a prominent case study for scenario analysis. This study uses two newly developed global top-down and bottom-up models with a regional China focus to compare China's future energy and CO₂ emission pathways toward 2050. By harmonizing the economic and demographic trends as well as a carbon tax pathway, we explore how both models respond to these identical exogenous inputs. Then a soft-linking methodology is applied to "narrow the gap" between the results computed by these models. We find for example that without soft-linking, China's baseline CO₂ emissions might range from 15-20Gt in 2050, while soft-linking models results in 17Gt. Reasons for the results gap between the models are discussed subsequently, such as model structure and statistical inputs. At a sectoral level, the gap can be mainly traced to China's future coal use in electricity production. The study finds that it is beneficial to soft-link complex global models under harmonized assumptions. Although this study fails to "close the gap" between the two models completely, the experiences and insights shared here will be beneficial for researchers and policy makers that are drawing conclusions from the results of China and global scenario studies.
Closing the Loop for Aluminium Cans: Life Cycle Assessment of progression in Cradle-to-Cradle certification levels

Despite their different scopes, both the Life Cycle Assessment (LCA) methodology and the Cradle to Cradle (C2C) Certified™ Product Standard can support companies in the implementation of circular economy strategies. Considering the case of aluminum cans, the objectives of this paper are twofold: (i) to compare the environmental impact associated with different levels of two C2C certification requirements by using LCA; and (ii) to identify the main challenges and drawbacks in the combined use of LCA and C2C for packaging within the circular economy framework. Twenty different scenarios were developed and compared, according to three C2C certification levels, in terms of % renewable energy and % recycled content. The results show that increasing the recycled content provides more improvements to environmental impacts than increasing renewable energy usage. Furthermore, receiving a higher certification level does not necessarily mean environmental burden reduction in LCA sense. From a methodological point of view, the main challenge for LCA is to address the continuous loop of materials and account for the benefits from recycling in a consistent way. Meanwhile for C2C the challenge is to guarantee a proper translation of the C2C principles into the C2C certification program, avoiding burden shifting and to find a balance between the different certification requirements.

Combined nutritional and environmental life cycle assessment of fruits and vegetables
Nutritional health effects from the 'use stage' of the life cycle of food products can be substantial, especially for fruits and vegetables. To assess potential one-serving increases in fruit and vegetable consumption in Europe, we employ the Combined Nutritional and Environmental LCA (CONE-LCA) framework that compares environmental and nutritional effects of foods in a common end-point metric, Disability Adjusted Life Years (DALY). In the assessment, environmental health impact categories include greenhouse gases, particulate matter (PM), and pesticide residues on fruits and vegetables, while for nutrition we consider all health outcomes associated with fruit and vegetable consumption based on epidemiological studies from the global burden of disease (GBD). Findings suggest that one fruit/vegetable serving increase may lead to substantial nutritional health benefits even when considering uncertainty; 35 μDALY/serving fruit benefit compared to a factor 10 lower impact. Replacing detrimental foods, such as trans-fat and red meat, with fruits or vegetables further enhances health benefit. This study illustrates the importance of considering nutritional effects in food-LCA.

Comparative environmental and economic assessment of production, use and recycling of aluminium cans: Bologna vs Copenhagen

Circularity strategies need to be assessed both in terms of environmental and economic impacts, by performing full chain analysis, including the perspectives of producers, users and waste management operators. This study considered two different aluminium beverage can systems: Bologna and Copenhagen. We performed a combined Life Cycle Assessment (LCA) and Life Cycle Costing (LCC) analysis of the purchasing, production and waste management of beer aluminium cans, with the aim to compare the environmental and economic performances of the two systems and to identify potential misalignment in the integrated LCA-LCC analysis.

The comparative analysis of aluminium cans production, use, collection and recycling in the two systems showed that the best option from an environmental point of view is also leading to higher costs and trade-offs need to be considered in the decision making process.

Comparison of conventional Injection Mould Inserts to Additively Manufactured Inserts using Life Cycle Assessment

Polymer Additive Manufacturing can be used to produce soft tooling inserts for injection moulding. Compared to conventional tooling, the energy and time consumption during production are significantly lower. As the life time of such inserts is significantly shorter than the life time of traditional brass, aluminium, or steel inserts, multiple inserts might be needed to produce a large number of parts.

In an ongoing study, a simplified Life Cycle Assessment has been carried out in order to provide information on how the four alternative insert materials perform in comparison in terms of their potential environmental impact and yield throughout the development and pilot phase. Insert geometry is particularly advantageous for pilot production and small production sizes.

In this research, Life Cycle Assessment is used to compare the environmental impact of soft tooling by Additive Manufacturing (using Digital Light Processing) and three traditional methods for the manufacture of inserts (milling of brass, steel, and aluminium) for injection moulds during the pre-production phase.
Compatibility of the SE4ALL Energy Efficiency Objective with Renewable Energy, Energy Access, and Climate Mitigation Targets

The objectives of the Sustainable Energy for All (SE4ALL), a United Nations (UN) global initiative, are to achieve, by 2030: 1) universal access to modern energy services; 2) a doubling of the global rate of improvement in energy efficiency; and 3) a doubling of the share of renewable energy in the global energy mix (United Nations, 2011; SE4ALL, 2013a). The purpose of this study is to determine to what extent the energy efficiency objective supports the other two objectives, and to what extent the SE4ALL objectives support the climate target of limiting the global mean temperature increase to 2°C over pre-industrial times. To accomplish this, pathways are constructed for each objective, which then form the basis for a scenario analysis using the Energy Technology System Analysis Program TIMES Integrated Assessment Model (ETSAP-TIAM). We find that, in general, the energy efficiency objective is reinforced by the renewable energy objective, but not by the universal access objective. Achieving the energy efficiency objective is made cheaper (in terms of the net present value of investment costs) when the renewable energy target is also achieved. However, achieving both the renewable energy and energy efficiency targets require more investment than achieving the renewable energy objective alone. Furthermore, we find that the universal access objective requires much more investment in the residential sectors of developing regions of the world, and makes the meeting the other two objectives more expensive. Meeting any of the objectives also requires increased investment in the transportation sector. While achieving the SE4ALL objectives does not limit warming to 2°C on its own, it makes a substantial contribution toward that goal, particularly if the renewable energy and energy efficiency objectives are met.

Complexity management in the food industry

The many stakeholders in the food industry with their diverse interests make this industry complex and interesting to work with. There are four main stakeholders; 1) The customers with their increased demand for customized products, quick delivery times and increased responsiveness, 2) The authorities with increased legislations, 3) Employees with salary demands and 4) owners/shareholders with profit wishes add to the complexity. Furthermore, markets are getting bigger and the competition harder. The profit margin for many companies is getting smaller. There are a demand for quantifying this complexity and finding a method for using these complexity factors in economic calculations. The research question this paper seeks to address is therefore “Which complexity factors can be quantified in the food industry and how can they be used in economic calculations?” A case study of a SME Danish bread producer will address the research question due to the explorative nature of this study and the limited amount of previous research within this field.
Comprehensive assessment of fruits and vegetables human health effects in a LCA context

Nutritional effects from the 'use stage' of food items life cycle can have a substantial effect on human health; yet, they are often not considered in life cycle assessment (LCA). In our study we explore the case of increased fruit and vegetable consumption, a healthy dietary option – that could result in higher exposures to a wide variety of pesticides – and investigate the trade-offs between associated environmental and nutritional health effects. Methods:

We employ the Combined Nutritional and Environmental Life Cycle Assessment (CONE-LCA) framework that evaluates and compares in parallel the environmental and nutritional effects of foods expressed in Disability Adjusted Life Years (DALYs). For the environmental health assessment we consider impact categories such as global warming and particulate matter (PM) as well as chemical exposure due to pesticide residues. Global warming and PM are assessed following a traditional LCA approach. For the pesticide residue exposure, we use publically available health impact scores derived from toxicological studies of numerous pesticide active ingredients. For the nutritional assessment we focus on the various health outcomes considered in the global burden of disease that are based on epidemiological studies.

Results and discussion: Adding one serving of fruits or vegetables to the current average diet in Europe may lead to substantial nutritional health benefits. These nutritional benefits are slightly increased when we consider substitution scenarios in which the substituted food items are associated with negative health effects, such as red meat and trans-fat. Overall environmental health impacts associated with this addition are substantially smaller compared to nutritional benefits in each scenario, even when considering an uncertainty factor of 400 for the impacts of pesticide residues. Conclusion: The present study illustrates the importance of considering nutritional effects of food items in LCA. Our preliminary results suggest that nutritional health effects of food items can be substantial and comparable to environmental impacts, especially for nutritional foods such as fruits and vegetables. This approach could be used for making recommendations about sustainable diets and food choices.

Consumer Behavior towards Scheduling and Pricing of Electric Cars Recharging: Theoretical and Experimental Analysis

This article-based dissertation consists of five self-contained chapters. The first chapter presents the motivation of the dissertation and a summary of the four papers containing the dissertation. Three of the chapters are applied microeconomics papers dealing with the economics of recharging electric cars. The last chapter deals with analysis of energy consumption rate and its determinants of electric cars under the hands of customers. A variety of techniques are used including analysis of field data, economics laboratory experiments and theoretical modeling with simulation.

Chapter one presents an introduction to the main parts of the dissertation and a summary of the articles containing the dissertation.

Chapter two, 'The Economics of Workplace Recharging', proposes a microeconomic model of the demand for and supply
of recharging facility at workplace (WPC), and uses the approach to shed light on the incentives and barriers employees and employers face when deciding on the demand for and supply of WPC. Using the model and simulation, the paper also examines the existence of WPC market under the current prices, and finds that no WPC contract exists that an employer is willing to offer and, at the same time, that the majority of employees are willing to accept. To overcome the lack of demand for or under-provision of workplace recharging, various remedies are discussed and suggested.

Chapter three, ‘Myopic Loss Aversion Behavior under Ultimatum Game Framework in the Scheduling and Pricing of Electric Vehicle Recharging’, proposes, and tests at laboratory, contracts about recharging BEVs combining the ultimatum game framework and the myopic loss aversion (MLA) behavioral hypothesis. The model represents the behavior of EV-owners trading-off between the amount of the discount on fee for postponing recharging, the risk of being eligible to the discount and the risk of not recharging the BEV on time for unforeseen trips. Findings from the experiment show that indeed individuals perform decisions exhibiting MLA behavior. The intuition from the result is that presenting time-of-use recharging price as long-term contracts may curtail MLA behavior and help BEV owners to choose cost minimizing recharging time and, simultaneously, may help to reduce BEVs impact on the electricity grid system.

The fourth chapter, ‘Using the Peer Effect in Scheduling and Pricing Electric Vehicles Recharging: Laboratory Evidence about Peer Effect in Risk-Taking’, presents experimental evidence about peer effect in risk taking in general and, in particular, the use of peer effect in scheduling BEVs recharging. The study investigates whether individuals want to see the choices of others, if observing peers’ choices influences the observers’ choices, to what extent the peer effect is pervasive and who are being influenced by peers’ choices as well as the role the type of peer information plays on peer effects. The results show that a lion share of individuals want to see peers’ choices, but only a moderate percentage of them, mostly those with relatively lower scores in our math test (usually used to test cognitive ability) and lacking self-confidence, use the peers’ choices to revise their intrinsic choices. The results reveal also that the type of peer information plays a significant role in peer effects.

The fifth chapter, ‘Harnessing Big-Data for Estimating the Energy Consumption and Driving Range of Electric Vehicles’, analyzes the electricity consumption of BEVs and its sensitivity to the various driving environments in the hands of customers. The results show that the energy consumption rate of BEVs is highly sensitive to weather conditions and to driving styles. The results may help individuals to make informed decisions about BEV choice, manufacturers to build trust with customers by provide more accurate information, and governments to design policies based on reliable information.

Contribution of waterborne nitrogen emissions to hypoxia-driven marine eutrophication: modelling of damage to ecosystems in life cycle impact assessment (LCIA)

Marine eutrophication refers to the ecosystem response to the loading of a growth limiting nutrient, typically nitrogen (N), to coastal waters, where it may cause several impacts. One of the possible impact pathways to these impacts involves the excessive depletion of dissolved oxygen (hypoxia) in bottom waters. Hypoxia is identified as an important and widespread cause of disturbance to marine ecosystems and has been linked to the increasing anthropogenic pressure. This is driven by environmental emissions of reactive nitrogen, mainly from N-containing fertilizers used in agriculture and atmospheric deposition as a consequence of fossil fuels combustion.

Control and trust impact on outsourcing

This paper examines the relationships between control, trust and inter-organizational learning in outsourcing relationships, focusing on the question: How do different trust and control strategies affect the sharing and withholding of knowledge between client and vendor? Four studies are conducted; one, a large international client company and three of its vendors. Based on these cases and a literature review, various trust and control strategies are examined, and factors influencing the mutual knowledge interaction are identified. The results show an internal disagreement among managers in the client company similar to the general disagreement between proponents of cost transaction theory and relational exchange theory respectively. The vendors express no hesitation to withhold especially proactive knowledge of relevance for the client when they are dissatisfied by the information and/or trust level offered by the client. Implications for more optimal client vendor relationships are developed as well as suggestions for further research.

Control Structures in supply chains as a way to manage unpredictable cyber-risks

Supply chain growth, and their dependence on Information Technology (IT), is making cyber risks an increasingly unmanageable threat through traditional risk assessment methods. Systemic analysis methods have been identified as alternatives to traditional methods. This paper analyzes the application of a systemic risk analysis methodology to understand cyber risks in the supply chain. A generic supply chain is analyzed, and information flows, dynamic structures and the influence of cyber-attack on these are identified. This paper argues that a systemic approach is more efficient in detecting vulnerabilities, enabling an evolving disruption response process and culture in the supply chain.
COPE-SMARTER - A decision support system for analysing the challenges, opportunities and policy initiatives: A case study of electric commercial vehicles market diffusion in Denmark

Stakeholder's strategies in encouraging wide-scale market penetration depend on their perceptions. This study focuses on perceptions of Danish practitioners in policy-making organizations regarding the perceived challenges, opportunities and policy initiatives for the majority-market adoption of electric commercial vehicles (ECVs) in commercial sector in Denmark. We propose a new four-step expert-based technique, named COPE-SMARTER, for evaluating the market diffusion of environmental friendly technologies by combining SWOT analysis and multi-criteria decision analysis (MCDA) techniques. We focus on the perceptions regarding: (i) the potential promotional strength of motivators for ECV market penetration, (ii) the severity of the technological, financial, physical and operational challenges, (iii) the efficiency of policy initiatives in encouraging the market diffusion of ECVs, (iv) the expected market penetration rates for ECVs by target year. The results show the strength of the COPE-SMARTER approach in generating a clear, coherent, and tractable evaluation. Severe challenges are financial, operational and technological, with high purchase prices being by far the most severe. The opportunities are financial and environmental, with overall savings in the long-term as the opportunity with the highest promotional strength. Effective policy initiatives are low registration fee for ECVs, state subsidies for the purchase or use of ECVs, and emission-based taxes.
Coproduire les services publics: Gouvernance palliative des inondations et citoyenneté en milieu périurbain à Pikine (Sénégal)

The recurring floods experienced in recent years by many urban centres in West Africa are not merely the consequence of global climate change. Large parts of the poor urban populations in West Africa often live in hazardous areas where urban planning is inadequate and where the public services, infrastructure and protective regulations that are needed in order to face flood issues are poorly provided. As a result, recurrent flooding reinforces existing social inequalities and the vulnerability of the urban poor. This does, however, not mean that the delivery of collective services related to flood response does not exist or that it is ungoverned. In order to cope with inefficient public service provision, the inhabitants often organize to ensure that flooding is addressed. This study shows that in Pikine, a city located at the outskirts of Dakar (Senegal), the governance of floods entails the daily coproduction of flood prevention and adaptation services, where users play an important and active role. The authors show that this ‘palliative governance’ has a direct impact on vulnerable populations’ capacity to cope with and adapt to recurrent flooding. The authors show that the informality that is essential to the coproduction of services should not be seen as an opposition to the State, but rather as essential to the daily functioning of the state, as well as a manifestation of ordinary citizenship by residents of deprived neighbourhoods.

Cost damping and functional form in transport models
Transport models allowing for cost damping are characterised by marginally decreasing cost sensitivities in demand. As a result, cost damping is a model extension of the simple linear-in-cost model requiring an appropriate non-linear link function between utility and cost. The link function may take different forms and be represented as a non-linear-in-parameter form such as the well-known Box–Cox function. However, it could also be specified as non-linear-in-cost but linear-in-parameter forms, which are easier to estimate and improve model fit without increasing the number of parameters. The specific contributions of the paper are as follows. Firstly, we discuss the phenomenon of cost damping in details and specifically why it occurs. Secondly, we provide a test of damping and an easy assessment of the (linear) damping rate for any variable by estimating two auxiliary linear models. This turns out to be an important guidance as the damping rate largely dictates which link functions are appropriate for the data. Thirdly, inspired by the Box–Cox function, we propose alternative linear-in-parameter link functions, some of which are based on interpolation of approximate Box–Cox end points, and others which are inspired by Taylor Expansions. The different functions are tested in simulation experiments and subsequently in a large-scale demand model based on more than 22,000 revealed preference observations. It is concluded that the use of properly specified linear-in-parameter functions gives good data fit and sometimes even outperforms the Box–Cox functions without increasing the number of parameters.

Coupled near-field and far-field exposure assessment framework for chemicals in consumer products

Humans can be exposed to chemicals in consumer products through product use and environmental emissions over the product life cycle. Exposure pathways are often complex, where chemicals can transfer directly from products to humans during use or exchange between various indoor and outdoor compartments until sub-fractions reach humans. To consistently evaluate exposure pathways along product life cycles, a flexible mass balance-based assessment framework is presented structuring multimedia chemical transfers in a matrix of direct inter-compartmental transfer fractions. By matrix inversion, we quantify cumulative multimedia transfer fractions and exposure pathway-specific product intake fractions defined as chemical mass taken in by humans per unit mass of chemical in a product. Combining product intake fractions with chemical mass in the product yields intake estimates for use in life cycle impact assessment and chemical alternatives assessment, or daily intake doses for use in risk-based assessment and high-throughput screening. Two illustrative examples of chemicals used in personal care products and flooring materials demonstrate how this matrix-based framework offers a consistent and efficient way to rapidly compare exposure pathways for adult and child users and for the general population. This framework constitutes a user-friendly approach to develop, compare and interpret multiple human exposure scenarios in a coupled system of near-field ('user' environment), far-field and human intake compartments, and helps understand the contribution of individual pathways to overall human exposure in various product application contexts to inform decisions in different science-policy fields for which exposure quantification is relevant.

Current and future prospects for heat recovery from waste in European district heating systems: A literature and data review

Municipal solid waste has seen increasing annual volumes for many decades in contemporary Europe and constitutes, if not properly managed, an environmental problem due to local pollution and greenhouse gas emissions. From an energy perspective, waste is also an alternative fuel for power and heat generation; energy recovery from waste represents an effective measure to reduce landfilling and avoid disposal emissions while simultaneously reducing the equivalent demand for primary energy supply. A key factor for obtaining the full synergetic benefits of this energy recovery is the presence of local heat distribution infrastructures, without which no large-scale recovery and utilisation of excess heat is possible. In this paper, which aims to estimate municipal solid waste volumes available for heat recovery in European district heating systems in 2030, a literature and data review is performed to establish and assess current and future EU (European Union) waste generation and management. Main conclusions are that more heat can be recovered from current Waste-to-Energy facilities operating at low average heat recovery efficiencies, that efficient incineration capacity is geographically concentrated, and that waste available for heat recovery in 2030 is equally determined by total generation volumes by this year as by future EU deployment levels of district heating.
Cycling in multimodal transport behaviours: Exploring modality styles in the Danish population

Multimodality is important for achieving less car dependent lifestyles and more sustainable transport behaviours. It is widely recognised that cycling plays a prominent role in sustainable transport. However, research has largely focused on cycling substituting motorised transport. This study explores how cycling forms part of multimodal transport behaviour based on survey data on transport modes and travel purposes and the weekly frequency of out-of-home activities and travel mode use in a representative sample of adult Danes (n = 1957). The following five distinct multimodal travel segments or 'modality styles' are identified: 'education transport'; 'public-based transport'; 'limited transport'; 'bicycle-based transport'; and 'car-based transport'. Travel behaviour is predominantly multimodal with few unimodal car-drivers being identified. Substantial cycling takes place in all modality styles, and is embedded in a multimodal behaviour as the modality style combined cycling with several other modes. Furthermore, the study demonstrates that cycling serves many purposes that transgress the division of utility cycling and recreational cycling, and that cycling takes place in both dense urban settings and small towns. Thus, the way in which travel modes relate to the urban environment and variations in modality styles must serve as the starting point for policies aiming to fulfil the potential of multimodal transport behaviour and promote cycling. Danish Act on Processing of Personal Data, in a Smart Cities Research Perspective
The Danish act on processing of personal data influences what data can be processed for. Data has been collected with consent from the data subject for a specific purpose. Any other use of the data violates the purpose and requires new consent from each data subject. But the law does include some areas which are favorable for some position, science is one. This poster explains what the law says about processing data from a research point of view.

Decarbonising the Swedish transport sector with electricity or biofuels
Sweden has set long-term energy policy targets which aim at eliminating net greenhouse gas (GHG) emissions by 2050 [1]. Since the production of power and district heating in Sweden is already close to being carbon neutral, a further reduction of GHG emissions have to be sought in other sectors, for example the transport sector. By 2011, approximately 90% of the total fuel consumption in the transport sector stems from fossil fuels, accounting for around 45% of the GHG emissions in Sweden [1]. Therefore, the Swedish transport sector will have to face a major transformation in the next future, if the ambitious targets of a carbon neutral transport system by 2050 and of being independent from fossil fuels in the vehicle fleet by 2030 have to be achieved [1]. To meet the energy policy targets, radical restructuring of the fuel use and vehicle stock in the transport sector is required. In this context, this paper develops two alternative scenarios for the transport sector by 2050 – an Electric Vehicles Scenario (EVS) which include a high percentage of electric vehicles and a BIOfuel Scenario (BIOS) with a high percentage of biofuels. The scenario results are compared to the Carbon Neutral Scenario (CNS), adopted from the Nordic Energy Technology Perspective (NETP) 2013 [2]. The alternative scenarios for the transport sector are developed by means of an energy system model which includes the power, heat and transport sectors, taking into account possible synergies among the sectors. The energy system model computes the socio-economic value of the total annual system cost which then allows for a comparative analysis between the investigated scenarios.

Decision-support tools for climate change mitigation planning
This document describes three decision-support tools that can aid the process of planning climate change mitigation actions. The phrase ‘decision-support tools’ refers to science-based analytical procedures that facilitate the evaluation of planning options (individually or compared to alternative options) against a particular evaluation criterion or set of criteria. Most often decision-support tools are applied with the help of purpose-designed software packages and drawing on specialised databases. The evaluation criteria alluded to above define and characterise each decision-support tool. For example, in the case of life-cycle analysis, the evaluation criterion entails that the impacts of interest are examined across the entire life-cycle of the product under study, from extraction of raw materials, to product disposal. Effectively, then, the choice of decision-support tool directs the analysis towards a specific type of decision criterion.

Deconstructing the concept of renewable energy-based mini-grids for rural electrification in East Africa

The goal of providing universal energy access to all by 2030 under the UN-led SE4ALL initiative calls for new and innovative solutions to rural electrification and is fuelling the recent interest in mini-grids. Mini-grid solutions are emerging as a third alternative to rural electrification, coming between the option of large-scale grid extension and pico-scale stand-alone solutions like solar home systems or solar lanterns. International expectations of mini-grids are high, with the International Energy Agency suggesting that they will play a significant role in reaching the goal of universal access.

Based on a detailed review of past, ongoing, and planned mini-grids in East Africa, this study seeks to deconstructs the popular notion of mini-grids for rural electrification in East Africa. The study reveals that so far activities carried out under the heading of mini-grids to a large extent consist of the hybridization of existing utility-owned electricity systems for medium-size towns located far from the grid, which does not necessarily contribute to rural electrification. However, limited but increasing activity is identified regarding the use of mini-grids to bring electricity to rural villages and smaller rural towns. This is of specific interest because it is for this type of mini-grid that the main challenges are to be found with respect to identifying and testing adequate financing, ownership, and business models. Based on the trajectories identified for mini-grids for rural electrification and the challenges identified in the literature, the study concludes by proposing three avenues for further research. **Defining Interactions and Interfaces in Engineering Design**

This PhD thesis focuses on the understanding and definition of interactions and interfaces during the architectural decomposition of complex, multi-technological products. The Interaction and Interface Framework developed in this PhD project contribute to the field of engineering design research.

Developing complex, multi-technological products involves the joint effort of multiple engineering disciplines in order to arrive at an end product, which satisfies its requirements. A major challenge is however the fact that bringing together engineers from different technical backgrounds means that they have different conceptual viewpoints on the product and use different ‘technical languages’ to communicate. Some terms like an interface, is used frequently in engineering however with no commonly declared meaning and is thus subject to much interpretation across engineering disciplines. It is well-known that most problems arise at the interfaces during product development, which is why there is a need for a rigorous and multi-disciplinary treatment of the concept of interfaces as well as interactions.

On the basis of a two-year case study at a medical device manufacturer, the role of interactions and interfaces in product family development has been investigated. The case study showed that for this particular case, interaction and interface descriptions represents the rationales needed to reuse documentation across multiple product variants. The interaction and interface descriptions thus become documents of legal matter and must therefore be unambiguously and completely described.

Following this observation, a comprehensive and systematic literature review has been performed in order to investigate the definition and perception of an interface. The review resulted in a classification revealing 13 dominant perceptions of what an interface is from an academic perspective including the observation of an apparent confusion between the terms interaction and interface. In addition, a case example of a solenoid valve was examined in order to reason out the likely causes of problems occurring at interfaces. The case example showed that interfaces that reside at the boundary between engineering disciplines are vulnerable to misinterpretation and rework.

Based on this understanding, this thesis presents a first principles, physics–based Interaction and Interface Framework, which provides a ‘common language’ across any engineering discipline for describing and communicating about interactions and interfaces in engineering design. The framework contains classifications of three key terms; interaction, interaction mechanism, and interface. Due to the first principles, physics–based approach to deriving the framework, it has been possible to arrive at a classification of interaction mechanism, which is mutually exclusive (no overlap) and collectively exhaustive (no gaps). This contribution changes the existing paradigm of reasoning about interactions and allows for an unambiguous architectural decomposition of a product.

The framework further proposes an 8–step architecting approach explicitly articulating how to systematically apply the framework top-down thus enabling complete and unambiguous descriptions of interactions and interfaces throughout the system. A tool called an Interaction Specification Wheel (ISW) is introduced to support consistency in writing requirements and specifications. All of the contributions have been evaluated in an initial test, which indicated a positive effect on their ability to capture interactions and unambiguously specify them. Further research is needed to obtain statistical significance. Future research may investigate how to incorporate the framework into practice and further evaluate the high level effects. This will most likely require two or more case studies in real-life projects.
Design and optimization of flexible multi-generation systems
This thesis focuses on the design of flexible multi-generation systems, which are dynamic and integrated energy conversion systems characterized by the ability to adjust operation in response to fluctuating operating conditions. It is the hypothesis that these systems may support the balancing of variable renewable energy sources in a cost-effective way by linking the different sectors in the energy system with local energy supply systems. A key challenge faced in the development of flexible multi-generation system is the knowledge gap between process design practices, which simplify energy system variations and dynamics, and energy system analysis, which fails to consider process integration synergies in local systems. The primary objective of the thesis is to derive a methodology for linking process design practices with energy system analysis for enabling coherent and holistic design optimization of flexible multi-generation systems. A methodology is presented for optimizing the design of flexible multi-generation systems which considers: Selection, dimensioning, location and integration of processes; operation optimization with respect to both hourly variations in operating conditions as well as long term energy system development; biomass supply chains and local resource availability; combined with global sensitivity and uncertainty analysis. The methodology includes a novel method for aggregating external operating condition datasets, named the CHOP method. In addition, three case studies focusing on integrating biomass processing and energy conversion technologies in existing combined heat and power plants in Denmark are conducted using the developed methods. The outcomes of this thesis indicate that the developed design methodology is efficient in screening for promising designs of flexible multi-generation system. In addition, the case study results emphasize the importance of considering flexible operation, systematic process integration, and systematic assessment of uncertainties in the design optimization. It is recommended that future research focus on assessing system impacts from flexible multi-generation systems and performance improvements from storage options.
translating the hiring of a designer into aesthetic innovation? We use a unique dataset containing information on firms, their hiring of designers, and their aesthetic innovation activity measured by design applications (design patents). Our findings show that hiring a designer does increase the likelihood of producing an aesthetic innovation. Hence, designers re a determinant of aesthetic innovations. However, in order to benefit fully from hiring a designer the firm needs prior experience in aesthetic innovation.

**Designer's Identity: Personal Attributes and Design Skills**

A designer’s professional identity (DPI) develops through both education and professional experience, building on core personality traits and innate skills. In this paper a systematic literature review and a secondary narrative review were developed in order to map personal attributes and design skills that comprise the DPI. Just a few works in literature dealt with these two elements holistically. Thus, in order to address this gap a holistic understanding of these elements, in context, is proposed as a cohesive framework where a DPI can be described as it evolves over time.

**Design for Sustainability and Project Management Literature – A Review**

The growing pressure on natural resources and increasing global trade have made sustainability issues a prime area of concern for all businesses alike. The increased focus on sustainability has impacted the way projects are conceived, planned, executed and evaluated in industries. Since project management literature has hardly been considered in design for sustainability research, this article attempts to review the points of intersection between these two fields, and explores the potential that knowledge from project management literature has in improving efficiency and effectiveness of development and implementation of design for sustainability tools.

Designing an Africa-EU research and innovation collaboration platform on climate change

Climate change is arguably the most significant of a set of interconnected global challenges threatening water resources and food security. In particular, the relationship between water resources, food systems and climate change is tightly coupled, and improved food security under climate change and climate variability scenarios requires globally coordinated actions for both technical and policy interventions to achieve greater resilience. Successful implementation of these actions requires a comprehensive scientific knowledge base delivered by extensive global collaboration, taking into account past and ongoing successful research and innovation initiatives. Diverse actors from all over the world—from corporations to governments and citizens—are increasingly recognising the urgent need to address climate change in their respective spheres of influence. This report is intended to contribute to making this process more effective by developing a proposition for a platform to strengthen Africa-EU research and innovation collaboration on climate change.

Detection of icing on wind turbine blades by means of vibration and power curve analysis: Icing detection in wind turbines

Ice accretion on wind turbines' blades is one of the main challenges of systems installed in cold climate locations, resulting in power performance deterioration and excessive nacelle oscillation. In this work, consistent detection of icing events is achieved utilizing indications from the nacelle accelerometers and power performance analysis. Features extracted from these two techniques serve as inputs in a decision-making scheme, allowing early activation of de-icing systems or shut down of the wind turbine. An additional parameter is the month of operation, assuring consistent outcomes in both winter
and summer seasons. The amplitude of lateral nacelle vibration at rotor speed is the used condition indicator from vibration standpoint, which is verified by the presence of sinusoidal shape in high-resolution time waveforms. Employment of k-nearest neighbour on wind speed - power production data sets leads to successful recognition of power performance deterioration. Results from one wind park consisting of 13 turbines operating under icing are presented, where similar patterns on both vibration and power curve data validate the effectiveness of the proposed approach on the reliable detection of icing formation.

Developing a Support Tool for Global Product Development Decisions
This paper investigates how global product development decisions are made through a multiple-case study in three Danish engineering. The paper identifies which information and methods are applied for making decisions and how decision-making can be supported based on previous experience. The paper presents results from 51 decisions made in the three companies, and based on the results of the studies a framework for a decision-support tool is outlined and discussed. The paper rounds off with an identification of future research opportunities in the area of global product development and decision-making.

Development and implementation strategy for the of product configuration systems in engineer-to-order companies

This paper will address how to develop a strategy when developing and implementing product configuration systems (PCSs) in engineer-to-order (ETO) companies. PCSs are often gradually implemented especially where there are complex products and processes in order to break down the overall project and reduce risk. This highlights the importance of having an overall strategy to guide the long-term development and implementation of PCSs. In this paper, guidelines for making the strategy are provided and supplemented with examples based on a case study. The guidelines include the main objectives for the development and implementation process, PCSs to be used to support the sales and / or engineering processes, more uniform IT support for making product configurations, combining output from different PCSs and finally integrations that includes both internal and external IT systems. Based on this an overview of how PCSs can support the overall configuration process can be generated.

Development of a Simplified Process Integration Methodology for application in Medium-Size Industries

Achieving significant energy savings is fundamental for reaching the ambitious EU 20-20-20 environmental targets. Several methodologies based on the Pinch concept have proved to be highly effective for identifying and assessing energy savings possibilities in the industrial sector. However, saving opportunities may be missed in the case of medium-size industries. Applying these methods may indeed be costly and time consuming, as it can require large engineering efforts, e.g., for data acquisition. This paper presents a methodology based on process integration techniques, termed “Specific Savings Potential method” (SSP), to depict and promote energy savings in intermediate-size industries for plant retrofit. It builds on the idea that only few of the process streams in a factory should be considered for efficiency measures implementation with regards to economic and operational aspects. Three screening tools are introduced. They are based on engineering experience and simple mathematical criteria, including both thermodynamic and economic considerations. Moreover, possibility of using less accurate data or estimates is discussed, since data acquisition is a severely time-consuming task in retrofit projects. This novel methodology is applied to a Danish dairy factory: the results and the method itself are compared with conventional pinch analysis. The findings show that the SSP method is a tool able to simplify and shorten the conventional pinch technique, while depicting the most promising savings opportunities: in the case study a reduction in energy use of 24% is achieved when only considering 24 process streams out of 62. In this sense, it has the potential of promoting the application of PI tools in the industry, especially in medium-size industries where budgets for external consultants are generally low.
Differences and similarities of energy innovation systems – comparison of five technology areas in Denmark

This paper presents a study of the energy innovation systems concerning five technology areas in Denmark: biomass energy, wind power, solar cells, fuel cells & hydrogen and energy efficiency technology. The study shows that the characteristics of the innovation systems differ significantly between the areas amongst other things concerning actor landscapes, market formations, and patterns of learning and interaction. This is despite the common context of Danish society and Danish energy systems, policy and institutions. An increase in maturity has appeared in some of the areas over the latest decades. Along with the increase in maturity, a number of new challenges have appeared. Despite internationalization and open economies, the national, domestic level is of significant importance. The paper contributes to current research discussions on the context relations of technological innovation systems, including the significance of the international dimension and the relationships to the established energy sector and incumbents.

Different Pathways for Achieving Cleaner Urban Areas: A Roadmap towards the White Paper Goal for Urban Transport

The 2011 White Paper on Transport of the European Commission spells out a series of targets for 2030 and 2050. One of the 10 targets is explicitly related to urban transport and stipulates: "Halve the use of 'conventionally fuelled' cars in urban transport by 2030; phase them out in cities by 2050. Achieve essentially CO2-free city logistics in major urban centres by 2030." With this paper we present and discuss a roadmap that deals with the question who needs to do what by when in order to reach the White Paper goal for urban transport. The "stakeholder-driven" roadmap was developed in the FP7 project TRANSFORuM. The paper will present the key findings and the suggested action steps identified in the roadmap. The paper will also exemplify three possible urban transformation pathways towards the urban target. This approach emerged from stakeholder consultations which highlighted the need to take into account the widely differing conditions among European cities.

District heating as a source of flexibility in the Nordic electricity market

The present share of variable renewable energy (VRE) generation such as wind power and solar photo voltaic is relatively high in many of the Nordic countries. E.g. wind power generated 42% of the annual electricity consumption in Denmark in 2015. The share of VRE is expected to increase in the years to come in order to reach the ambitious renewable energy deployment targets in the Nordic and Baltic countries. Transformation to an energy system increasingly based on VRE will escalate the requirement for flexible operation of the entire energy system, including improved integration among energy sectors. District heating (DH) is an important sector in the Nordic energy system and has a large potential for increased flexible operation in relation to the future electricity system. This potential is only partly exploited today. One reason for this is the differences in regulatory framework conditions for DH compared to the electricity market, e.g. different energy taxes, which may hinder the potential benefits from systems integration and lower the realisable potentials.

District heating as the infrastructure for competition among fuels and technologies

The present share of variable renewable energy (VRE) generation such as wind power and solar photo voltaic is relatively high in many of the Nordic countries. E.g. wind power generated 42% of the annual electricity consumption in Denmark in 2015. The share of VRE is expected to increase in the years to come in order to reach the ambitious renewable energy deployment targets in the Nordic and Baltic countries. District heating as the infrastructure for competition among fuels and technologies

District heating networks offer the possibility of competition between a wide range of fuels for combustion as well as technologies for comfort heat and cooling in buildings. For decades, cogeneration of electricity and heat for industrial processes or district heating has been a key technology for increased energy efficiency. Additional technologies suitable for small-scale networks are heat pumps, solar panels and local biomass in the form of straw or biogas. For large-scale urban networks, incineration of urban waste and geothermal heat are key technologies. With heat storages district heating infrastructure can contribute significantly to balancing the intermittency of wind power.

This paper is an update of the authors' article published in Energy Policy in 2003 focusing on the European directives focusing on competition in the electricity and gas network industries and promotion of renewables and cogeneration but limited support for the development and expansion of the district heating infrastructure. It was partly based on a contribution to the Shared Analysis Project for the European Commission Directorate-General for Energy, concerning the penetration of combined heat and power (CHP), energy saving, and renewables as instruments to meet the targets of the Kyoto Protocol within the liberalised European energy market.

The update will focus on recent research on district heating in North Europe, which covers not only the physical infrastructure, but also the very important immaterial infrastructure, such as the legal and institutional framework. This includes the experience with market places for electricity trade on an hourly basis over the last two decades. Improved modelling tools and modelling experience will add to the development and performance of district heating systems.

Finally, we summarise the tasks for a European policy concerning the future regulation of district heating networks for CHP, emphasising the need for rules for a fair competition between natural gas and district heating networks and the need for integration between energy systems.

Does habitual behavior affect the choice of alternative fuel vehicles?

Because of the recent improvements in the electrification process of cars, several types of alternative fuel vehicles are appearing in the car market. However, these new engine technologies are not easily penetrating the market around the world and the conventional ones are still the leaders. A vast literature has explored the reasons for such low market penetration, due mainly to car's features. Using a hybrid choice model approach, in this research we study if, and to which extent, habitual car use influences individual propensity to buy a specific type of engine technology. We found significant latent habitual effect on choices of type of car engine. This effect is important only for some of the car alternatives.
considered in the study. In particular, habitual car users prefer to buy a new car with liquefied petroleum gas and compressed natural gas types of engine technology instead of a conventional one. The importance of taking into account this latent construct is demonstrated also with the results of the simulated elasticity measures. In fact, the exclusion of latent habitual effect significantly underestimates the elasticity of diesel and hybrid cars and overestimates the elasticity of liquefied petroleum gas car.

Do rich households live farther away from their workplaces?
One of the classic predictions of urban economic theory is that high-income and low-income households choose different residential locations and therefore, conditional on workplace location, have different commuting patterns. The effect of household income on commuting distance may be positive, because of an increased demand for housing as house prices are lower further from workplace locations, or negative, because of an increase in the value of travel time. In addition, the sign of this effect may depend on the location of residential amenities relative to workplaces. Empirical tests of this effect are not standard, due to reverse causation and lack of good control variables. To address reverse causation, this effect is derived using changes in household income and distance through residential moves keeping workplace location constant. Our results contradict previous results in the literature. We show that for Denmark, conditional on the workplace location, the income elasticity of distance is negative and in the order of 0.18. This elasticity is larger for single-earner than for dual-earner households. Conditional on that the household moves residence between municipalities, the elasticity is suggested to be around 0.60.

Drivers of cycling mode-share: analysis of danes travel behavior 1996-2013

Denmark, as Europe’s second cycling nation after the Netherlands, has a cycling mode share of around 15% of all trips. Cycling was decreasing slowly through the 1990s into the 2000s, which inspired substantial investments and promotional efforts to reverse the trend. This paper uses Danish micro-level travel survey data series from 1996 through 2013 to analyze the trend in cycling as main or access mode, as well as the significance of background variables representing key spatial and societal trends. The analysis confirms that the general trend in cycling from 1996 to 2013 was negative irrespective of statistical control for socio-economics, ageing, location, urban density, and weather. Results points to an increasing significance of population density over time as well as changes to the effect of location vis-a-vis the largest urban centers. The difference in cycling between central areas and more peripheral areas is growing. Other changes include a decreasing ‘income divide’ in cycling as well as a decreasing retirement effect. Results are presented and discussed. (C) 2016 Published by Elsevier B.V. This is an open access article under the CC BY-NC-ND license.

Driving Cessation Anno 2010 Which Older Drivers Give Up Their License and Why? Evidence From Denmark

This study focuses on the decision to either stop or continue driving among a cohort of Danish seniors whose driving licenses expire, for the first time, at the age of 70. Based on 1,537 standardized telephone interviews with licensed drivers, we compared persons who intended to renew or not to renew their licenses. The results partly recapture the findings of earlier studies. However, in contrast to former cohorts, a much higher percentage of older drivers intended to keep their licenses. The strongest factors predicting the intention to renew were active car use, feeling safe as a driver, and not having illnesses that impaired driving ability. Three of these factors were strongly correlated with gender, indicating that efforts to prevent premature driving cessation should especially focus on increasing women’s confidence and experience in driving.

Drying of a tape-cast layer: Numerical modelling of the evaporation process in a graded/layered material

Evaporation of water from a ceramic layer is a key phenomenon in the drying process for the manufacturing of water-based tape cast ceramics. In this paper we present a coupled free-flow-porous-media model on the Representative Elementary Volume (REV) scale for coupling non-isothermal multi-phase compositional porous-media flow — for the ceramic layer — and single-phase compositional laminar free flow — for the air above it. The preliminary results show the typical expected evaporation behaviour from a porous medium initially saturated with water, and water–vapour transport to the free-flow region in accordance with the available results from the literature. We elaborate on and discuss the characteristic drying-rate curve for a single layer ceramic, and compare it with that of a graded/layered ceramic. We, moreover, show the influence of the mean diameter of particles of the porous medium (dp) — which directly affects the intrinsic permeability (K) based on the well-known Ergun’s equation — of each single ceramic layer on the drying behaviour of a graded/layered ceramic.

Dual boundary spanning: Toward a typology of outside-in open innovation in the Canadian context

The extant literature runs short in understanding openness of innovation regarding and the different pathways along which internal and external knowledge resources can be combined. This study proposes a unique typology for outside-in innovations based on two distinct ways of boundary spanning: whether an innovation idea is created internally or externally and whether an innovation process relies on external knowledge resources. This yields four possible types of innovation, which represent the nuanced variation of outside-in innovations. Using historical data from Canada for 1945–1980, this study unveils different implications of these innovation types for different levels of innovation novelty.

Dynamic optimization of building performance: Use of real-time building data for improving facilities management

In this digital age many companies consider data as new oil. It also includes facilities management organizations. Facilities managers in many private and public organizations are interested in data sets on building characteristics, operation and maintenance activities, usage patterns, space management, energy management, asset management etc.

The research focus of this industrial PhD is to study how these different building data sets can be used and combined for improving total value of buildings, with special emphasis on environmental building performance from lifecycle perspective.

The project follows the implementation of Integrated Facilities Management System KMD Atrium in Danish Facilities Management organizations. The focus is on non-residential buildings from user- and facilities manager perspective. By studying the implementation effects of KMD Atrium, this industrial PhD develops a methodological basis and purpose-based software for simultaneous calculation of total value and environmental performance of non-residential buildings.

So far, a literature study has identified 8 indicator categories that should be considered when addressing environmental performance of building: Energy, GHG emissions, Water, Waste management, Land use, Building materials, Reuse/recycling potential and Indoor Environmental Quality. The study indicates that research is mainly focusing on energy and GHG emission related topics, while other environmental categories are not investigated sufficiently.

The next step of the project combines research and practice through various case studies in which environmental building performance of non-residential buildings will be studied. Case studies will investigate which environmental indicators are used in practice and why, and disclose how building data related to these indicators is collected, used and combined.

Dynamic vehicle routing problems: Three decades and counting

Since the late 70s, much research activity has taken place on the class of dynamic vehicle routing problems (DVRP), with the time period after year 2000 witnessing an area explosion in related papers. Our paper sheds more light into work in this area over more than 3 decades by developing a taxonomy of DVRP papers according to 11 criteria. These are (1) type of problem, (2) logistical context, (3) transportation mode, (4) objective function, (5) fleet size, (6) time constraints, (7) vehicle capacity constraints, (8) the ability to reject customers, (9) the nature of the dynamic element, (10) the nature of the stochasticity (if any), and (11) the solution method. We comment on technological vis-à-vis methodological advances for this class of problems and suggest directions for further research. The latter include alternative objective functions, vehicle
speed as decision variable, more explicit linkages of methodology to technological advances and analysis of worst case or average case performance of heuristics.

Eating to save wild-life: is a truly conservation-minded zoo/aquarium a vegan zoo/aquarium?

According to the European Association of Zoos and Aquaria their mission is ‘to facilitate cooperation … towards the goals of education, research and conservation’. Livestock production is one of the leading causes of often-irreversible land use changes, greenhouse gas emissions, loss of biodiversity and different types of environmental degradation – all affecting wildlife negatively, and hence undermining conservation policies that aim to protect individuals, populations and species.

But what is the link between livestock production and zoos and aquariums? One link, putting it a bit boldly, could be: Does it make sense to work for conservation by preserving animal species in captivity while selling food to visitors that may be undermining this effort? Complicating the issue is that zoos and aquariums are dependent on generating a profit from ‘non-core’ services such as cafeterias and the like to generate funds for running the zoo, and conceivably, in turn for conservation purposes – funds that might diminish if zoos and aquariums do not sell a variety of food products, including animal-based ones to their visitors. The main question addressed by this paper is: If zoos and aquariums are to work for sustainability and species conservation – should food served in zoos be part of considerations – and to what extent? To answer this question the paper presents the goals of EAZA along with environmental impact profiles, relying on previously published life cycle assessments of the entirety (i.e. from cradle to gate) and across a multitude of impact categories (i.e. including and beyond climate change), of typical food items sold in zoos and aquariums. It describes the impacts on wildlife and nature that these products may have. Further we link this analysis to different ideas of sustainability, addressing the issue of how to balance positive and negative impacts of zoos and aquariums. Finally we discuss the educational opportunities that arise if food served in zoos and aquariums is seen as part of a conservation strategy – and the possible challenges such an approach faces.

**E-bike safety: Individual-level factors and incident characteristics**
As electrically assisted bicycles (e-bikes) become more widespread, the number of crashes in which they are involved is also growing. We used data from a survey of 685 e-bike users in Denmark to examine the factors which contribute to perceived e-bike safety and involvement in safety critical incidents. Using regression analyses, we demonstrated that riding style and e-bike attitude played a crucial role in both perceived safety and involvement in safety critical incidents. Age and female gender were negatively associated with perceived safety. 29% of participants had experienced at least one safety critical incident that they believed would not have happened on a conventional bike. The most frequent explanation offered for these situations was that other road users had underestimated the speed of the e-bike, followed by rider problems regulating e-bike speed. Older cyclists were more likely to report problems maintaining balance due to the weight of the e-bike. Preventive measures discussed include awareness campaigns and making it easier to distinguish e-bikes from conventional bicycles to address the problem of underestimation of speed. We also identified a need to familiarise with the e-bike before using it in demanding traffic situations.

**Ecodesign framework for developing wind turbines**
Despite a wind turbines perceived environmental benefits, there are still many improvements that can be made in the product development process to improve its environmental performance across life cycles. This is especially important as
the wind power industry continues to grow, both in volume and size, in response to increasing global market demands. Planning, implementing, monitoring, documenting and communicating product related environmental activities of wind turbines in a life cycle management context is the focal point of this article. The development and application of an ecodesign framework specific to the organizational context of Siemens Wind Power is described. The framework was developed using an iterative, action research design approach which relied on the participation of cross-functional employees. Five iterations occurred over a four year time frame and methods such as workshops, pilots, interviews and life cycle assessment were applied. The ecodesign framework was aligned with the company's formal product lifecycle management process. When combined with life cycle assessment, the framework can identify potential environmental improvements and contribute to coherent and transparent environmental target setting. Examples of this are demonstrated at the technological, organizational and societal levels of the company. Lessons learned obtained during the design iterations call for assigned responsibility through key performance indicators at project and functional levels; adaptive learning approaches to ecodesign based on continuous improvements; and additional capacity building amongst employees in life cycle thinking. The article proposes that a life cycle based ecodesign framework can be a driver for sustainable innovations in components, product systems, technologies and business models.

Ecodesign perspectives of thin-film photovoltaic technologies: A review of life cycle assessment studies

Here, we review 33 life cycle assessment (LCA) studies of thin-film photovoltaic (PV) technologies that have had a holistic coverage in their assessments and/or have included ecodesign aspects. Only five of them were found to have a comprehensive life cycle and impact coverage, and their analyses highlighted the importance of (i) including the entire life cycle of the PV system, in particular the often-omitted disposal stage, and (ii) assessing all relevant impact categories and not just climate change or energy requirements to minimise the risk of burden-shifting. Out of the 28 studies embracing ecodesign considerations in parts of the PV life cycle, the analysis of the eleven of them addressing primary energy demand during module production suggests that electricity consumption during the metal deposition processes is a top contributor and should be prioritised by PV technology developers. A similar analysis of the ten studies having included the balance of system components (BOS) in the assessments showed that these contribute significantly to most environmental impact categories. Beyond recommending that stakeholders in the PV field rely on LCA to support decision-making and to guide scientific research and technological development, we strongly advocate LCA practitioners to include the entire PV system, including the BOS, to identify ecodesign opportunities without risking potential burden-shifting across the different parts of the system and across impact categories.

Effect factors for marine eutrophication in LCIA based on species sensitivity to hypoxia

Hypoxia is an important environmental stressor to marine species, especially in benthic coastal waters. Increasing anthropogenic emissions of nutrients and organic matter contribute to the depletion of dissolved oxygen (DO). Biotic sensitivity to low levels of DO is determined by the organisms' ability to use DO as a respiratory gas, a process depending on oxygen partial pressure. A method is proposed to estimate an indicator of the intensity of the effects caused by hypoxia on exposed marine species. Sensitivity thresholds to hypoxia of an exposed ecological community, modelled as lowest-observed-effect-concentrations (LOEC), were compiled from literature for 91 demersal species of fish, crustaceans, molluscs, echinoderms, annelids, and cnidarians, and converted to temperature-specific benthic (100 m depth) LOEC values. Species distribution and LOEC values were combined using a species sensitivity distribution (SSD) methodology to estimate the DO concentration at which the potentially affected fraction (PAF) of the community's species having their LOEC exceeded is 50% (HC50LOEC). For the purpose of effect modelling in Life Cycle Impact Assessment (LCIA), effect factors (EF, [(PAF) m3 kgO2 -1]) were derived for five climate zones (CZ) to represent the change in effect due to a variation of the stressor intensity, or EF = ΔPAF/ΔDO = 0.5/HC50LOEC. Results range from 218 (PAF) m3 kgO2 -1 (polar CZ) to 306 (PAF) m3 kgO2 -1 (tropical CZ). Variation between CZs was modest so a site-generic global EF of 284 (PAF) m3 kgO2 -1 was estimated and may be used to represent the average impact on a global ecological community of marine species exposed to hypoxia. The EF indicator is not significantly affected by the major sources of uncertainty in the underlying data suggesting valid applicability in characterisation modelling of marine eutrophication in LCIA.
Effect factors for terrestrial acidification in Brazil

To support the increased use of existing Life Cycle Impact Assessment (LCIA) methodologies across the world, new methodological elements have been developed towards spatially resolved impact assessment.
Spatially resolved methods could better capture the differences of regional environmental conditions, which is an essential approach considering countries like Brazil, with high biodiversity. Previous studies have assessed the impacts of terrestrial acidification from the estimations of the potential losses of vascular plants species richness as a result of exposure to acidifying substances for 13 biomes, with 2409 species addressed for whole world. In this context this work aims to provide spatially-differentiated effect factors (EF) for terrestrial acidification in Brazil and support the development of spatially-differentiated characterization factors for Brazil. In order to maintain compatibility with existing LCIA methods the effect factors were developed using the framework adopted by LC-Impact and Impact World+ methods. Soil pH was used as an indicator of soil acidity to predict plant occurrences. From the number of plant species occurring at each 0.1 pH unit response relationships of species richness and soil pH were developed. The species richness in each ecoregion were transformed into an empirical potentially not occurring fraction, which is a zero-to-one measure used to represent the presence or absence of species. The set of data consists of 976345 records of plants occurrences in Brazil, represented by 33167 species, indicating that this is a comprehensive study. Maps of soil pH in Brazil were extracted at 1-km resolution and pH values were extracted for the depth range of 0-30cm. For each ecoregion, species richness was plotted against soil pH and the exposure-response curves for acidification described the behavior of plant species in a certain region when it is exposed to acidic conditions. From these curves it was possible to derive the effect factors for terrestrial acidification. The results of this work show that spatial differentiation is meaningful when it is possible to combine fine spatial resolutions and highly representative data and this approach can be applied for other impact categories and regions, and contribute to the development of spatial differentiated LCIA methodologies.

**Effect modifiers in intervention research at hospitals in three Nordic countries**

**Introduction:**
The impact of ergonomic interventions may be offset by other changes at the work place, primarily rationalizations. These have previously been shown to imply a dominant negative effect on health and risk factors, thus causing effect modification (Westgaard & Winkel 2011). The present paper aims to present assessment of potential effect modifiers in intervention studies at hospital wards in Denmark, Iceland and Sweden.

**Material and methods:**
The effect modifiers were assessed by a newly developed method (the EMA method; Edwards & Winkel 2016). It is a type of group interview including 3-6 participants representing all occupational groups in the investigated organization. The group is asked to write down significant changes at the workplace during the investigated period. The method also includes a semi-qualitative assessment of the potential Work Environment (WE) impact of each modifier. It aims to capture both the individual and collective account of all significant events that may have caused a significant impact in relation to the specific aim of the investigated intervention. Thirteen hospital wards went through interventions based on either the lean tool VSM (Value Stream Mapping) (6 wards) or the ErgoVSM method (Jarebrant et al, 2010) where additional focus is on ergonomic issues (7 wards).

**Results:**
In total 120 interventions were implemented. However, 322 significant modifiers were assessed to have occurred during the intervention period. Of these, 120 were assessed to imply impaired WE, 166 a positive impact, 33 no impact and 3 were not assessable. The number of significant modifier events varied between wards from 8-48, while the number of implemented interventions varied from 0-28. The semi-qualitative assessments suggested a major impact on WE due to modifiers. At seven wards the dominating impact of the modifiers was estimated to improve WE; at two wards the modifiers were estimated mainly to impair WE while four wards showed a mixture of modifiers, some estimated to improve and other to impair WE.

**Conclusion:**
Numerous effect modifiers occurred parallel to the investigated interventions. This jeopardizes any inference regarding impact of the investigated interventions on WE. The study thereby highlights the significance of considering effect modifiers in ergonomic intervention research.

Effekt af cykeltræningskursus for forældre
I Østrig har man udviklet et kursus, der har det formål at hjælpe forældrene til bedre at kunne træne og vejlede deres børn til at blive sikre cyklister. Kurset er blevet evalueret, og evalueringen tyder på, at kurset både bidrager til at øge forældrenes kompetencer og engagement i deres børns cykeltræning samtidig med at børnenes faktiske cykelfærdigheder forbedres. Det anbefales dog at foretage yderligere undersøgelser for at nuancere og cementere de positive resultater.

Effekten af distraktion ved manuel overtagelse af bilkørslen
En ny undersøgelse tyder på, at reaktionstid ikke er et godt mål for, i hvor høj grad bilisters kørsel bliver påvirket af distraherende aktiviteter i situationer, hvor bilisten skal overtage kørslen manuelt efter at have kørt i delvist automatiseret tilstand. Forklaringen kan være, at det at gribe efter et rat er en refleksagtig respons, der trækker på andre ressourcer end de kognitive og visuelle ressourcer, der er centrale for at køre sikkert.

Efficiency and Robustness in Railway Operations
Passenger railway transport is an effective means of providing high capacity transport that is energy efficient and has low emissions. As the population of Denmark grows and there is an increased request for mobility, there is a need for railway services offering greater capacity and more reliability. Offering these services presents a challenging sequence of planning problems for operators. These range from problems considered on a daily basis to planning for years in the future, with different problems interacting and influencing
Operations research methods can be used to effectively model, investigate, and solve railway planning problems. Despite advances in computational power these large problems are still challenging to solve, especially as more modelling detail is sought. Within a Danish context this thesis seeks to apply operations research methods to different planning problems beyond past approaches, and where applicable, investigate solution methods that place more focus on the passenger and passenger experience. To cater to the growing demand for rail transport, and compete with different modes of transport, Danish railway operators must offer a consistent, reliable service, that is well planned from both a passenger and operator perspective. This thesis therefore considers different planning problems within passenger railway considering robustness of the system, and efficiency and optimality from the point of view of the passenger or operator.

The contributions of the thesis are in the investigation of robustness in railway, the application of optimization to a number of railway planning problems, and a detailed consideration of the specific concerns of Danish railway services. These contributions are summarised in the introductory chapter, and in the latter part of the thesis are given in each chapter.

Emergence of an urban traffic macroscopic fundamental diagram
This paper examines mild conditions under which a macroscopic fundamental
 diagram (MFD) emerges, relating space-averaged speed to occupancy in some
area. These conditions are validated against empirical data. We allow local speed-occupancy relationships and, in
particular, require no equilibrating process to be in operation. This means that merely observing the stable relationship
between
the space-averages of speed, flow and occupancy are not sufficient to infer a robust relationship and the emerging MFD
cannot be guaranteed to be stable if traffic interventions are implemented.

Emergency Management involving Critical Infrastructure Disruptions: operationalizing the deployment of resilience
capabilities
Recent developments nurturing the importance of Emergency Management (EM) of Critical Infrastructure (CI) brought a
shift of emphasis from protecting the systems to building resilience. Resilience approach is required to cope with inevitable
events, ensuring ability to anticipate, absorb, adapt to, and/or rapidly recover from a potentially disruptive event. The study
proposes a novel approach to integrating the resilience capacities of CI into the EM cycle, which facilitates emergency
services and CI operators to collaborate in addressing resilience improvement measures, while planning to cope with CI
disruptions. It grounds on a previously published comprehensive framework which reflects the main characteristics of such
emergencies (e.g. interdependent, multi-sectoral, multi-stakeholder) and supports the identification, assessment and
development of specific technical and organizational capabilities. A pilot application is provided on a real case involving
the public and private actors engaged in the Regional Programme on Critical Infrastructure Protection and Resilience
(CIP-R) in Lombardy (Italy).

Employee motivation in Product-Service-System providers

This research investigates how intrinsic and extrinsic motivation factors contribute to employee motivation in providers of Product-Service Systems (PSS). Employee motivation determines the quality of the delivered service and is thus an area of great importance for PSS providers. We present rich case-based data collected through semi-structured interviews, a survey and secondary sources. The analysis showed the particularly high importance of intrinsic and individual motivation factors such as the fulfilling nature of the work and skill development showing the ownership and pride service employees took in their work. Further, the organisation needs to set the context of high employee motivation by enabling flexibility and performance feedback. Our research contributes to the literature by providing a first empirical study of employee motivation in PSS providers and thus providing important insights on the implementation of a servitisation strategy.

Energy and low carbon development efforts in Ghana: institutional arrangements, initiatives, challenges and the way forward

Over the years, Ghana has invested considerable effort and resources together with international partners to develop the energy sector and to mainstream energy low carbon pathways into national development plans. Low carbon development (LCD) provides a good opportunity, of not only building upon earlier energy and climate change local processes and structures but also help to mainstream low carbon agenda in economic activities and national development plans. For this to work however, require efficient institutions and effective institutional arrangements. Based on extensive literature analysis, personal communications and inputs from stakeholders, the paper highlights the key institutional arrangements, their interactions, challenges and proffers recommendations for improvements. To improve energy and low carbon development effort from the perspectives of institutional structures, would require, clearer institutional mandates, continuous improvements in institutional coordination (intra and inter), capacity and skills development, sustained visibility of the essence of energy and LCD at high political levels as well as engagement by civil societies. Equally important are the issues of finance, data availability and quality, monitoring and evaluation.

Energy Efficiency
This report was commissioned by REN21 and produced in collaboration with a global network of research partners. Financing was provided by the German Federal Ministry for Economic Cooperation and Development (BMZ), the German Federal Ministry for Economic Affairs and Energy (BMWi), the Government of South Africa, the Inter-American Development Bank (IDB), the United Nations Environment Programme (UNEP) and the World Bank Group. A large share of the research for this report was conducted on a voluntary basis.

Energy efficiency and renewable energy modeling with ETSAP TIAM - challenges, opportunities, and solutions
The objectives of the Sustainable Energy for All (SE4ALL), a United Nations (UN) global initiative, are to achieve, by 2030: 1) universal access to modern energy services; 2) a doubling of the global rate of improvement in energy efficiency; and 3) a doubling of the share of renewable energy in the global energy mix (United Nations, 2011; SE4ALL, 2013a). The purpose of this study is to determine to what extent the energy efficiency objective supports the other two objectives, and to what extent the SE4ALL objectives support the climate target of limiting the global mean temperature increase to 2°C over pre-industrial times. To accomplish this, pathways are constructed for each objective, which then form the basis for a scenario analysis using the Energy Technology System Analysis Program TIMES Integrated Assessment Model (ETSAPIAM). This presentation focuses on the modeling challenges including updating data, setting constraints, and reporting on
output. The presentation also addresses the addition of new model components such as traditional biomass and building energy efficiency.

This report collates a set of indicators, figures and tables for the energy innovation system in Denmark. Emphasis is on renewable energy and other technologies for moving towards sustainability. The purpose is to provide an overview of indicators available for illuminating dynamics and characteristics of energy innovation systems and to the extent possible offer figures in the individual indicators.
The report is an update of a report published in 2012. Graphs and numbers are updated with the most recent data available. The text is updated where needed in connection to the individual indicators as well as in the general remarks and conclusions. A limited number of new indicators and measurements are included. In addition, the accounts are in a few cases changed due to changes in data availability or in measurement methods.
The report is produced as part of the activities in “EIS – Strategic research alliance for Energy Innovation Systems and their dynamics – Denmark in global competition”. EIS is funded by the Danish Council for Strategic Research (Innovation Fund Denmark) and by the involved research organisations.

Entrepreneurial Orientation: The Dimensions’ Shared Effects on Explaining Firm Performance

We shed new light on the structure of the relationship between entrepreneurial orientation (EO) and firm performance and how this relationship varies across contexts. Using commonality analysis, we decompose the variance in performance—in terms of the effects of innovativeness, proactiveness, and risk taking—into parts that are attributable to unique variations in these dimensions (unique effects) and those attributable to covariation between these dimensions (shared effects). By demonstrating the empirical relevance of unique, bilaterally shared, and commonly shared effects in a heterogeneous sample of low-tech, high-tech, and multi-sector firms, we consolidate existing conceptualizations of EO and propose an extension of the extant theoretical views of the construct.
Environmental Assessment of Integrated Food and Cooking Fuel Production for a Village in Ghana

Small-scale farming in Ghana is typically associated with synthetic fertilizer dependence and soil degradation. The farmers often rely on wood fuel for cooking imported from outside the farmland, a practice that is associated with deforestation. Integration of food and energy production may be a holistic approach to solving these issues. We study four approaches to providing food and fuel for cooking in a small-scale farming community. Present practice (PP) of synthetic fertilizer based food production and provision of wood fuel from outside the farming area is compared to three modeled, integrated technology options: integrated food and household-scale biogas production (HH Biogas), integrated food and village-scale biogas production (Village Biogas), and integrated food and wood fuel production (Agroforestry). Integrated approaches are able to eliminate the import of wood fuel, reduce synthetic fertilizer use by 24%, 35% and 44% and soil loss by 15%, 20% and 87%, respectively, compared to present practice. An Emergy Assessment (EmA) shows that integrated approaches are relevant substitutes to present practice considering biophysical efficiency indicated by Unit Emergy Value (in solar emjoules (sej) per J of output) and dependence on renewable inputs indicated by the Global Renewability Fraction (in %): 2.6–3.0 × 10^5 sej/J and 38%–48% (PP), 2.5–2.8 × 10^5 sej/J and 41%–46% (HH Biogas), 2.4–2.6 × 10^5 sej/J and 45%–47% (Village Biogas), 1.7–2.4 × 10^5 sej/J and 49%–66% (Agroforestry). Systematic recycling and use of local resources may play a pivotal role in reducing the dependence on non-renewable resources in Ghanaian farming, ensuring long-term soil fertility and stemming the current deforestation of wood reserves.

Environmental Impact of Long Distance Travel

This paper presents an analysis of the CO2 emission resulting from long distance travel by Danes. The emissions are analysed as the Danes' footprint the whole way from Denmark to the final destination. International travel represents 31% of the Danes' CO2 emission from passenger travel and the climate burden from long overseas distances is especially high even though only few travel overseas. The travel activity is furthermore increasing much more for long distances than for European destinations. Domestic travel activity with overnight stay is nearly stagnating. The study furthermore shows that the Danish development is not especially outstanding compared to other countries.

Environmental impacts of flood control measures in climate change adaptation strategies

Because of climatic changes, large investments are needed to keep flood risk at an acceptable level in urban areas. Increasing dimensions of underground sewer systems and retention basins are increasingly supplemented with multi-functional approaches, aimed at managing water locally and/or route it on the surface without harming assets. When evaluating different adaptation approaches, a cost assessment is typically carried out, while environmental impacts usually are not considered. To close this gap, a Life Cycle Assessment (LCA) based method is developed, which allows to quantify environmental impacts of different storm water management strategies. It is tested with two different adaptation strategies for the Nørrebro catchment in Copenhagen, Denmark: A Cloudburst Management Plan (CMP), which uses a multi-functional approach and combines green infrastructure with subsurface pipes, and a Subsurface scenario (SSA), which uses only pipes and underground retention basins. To ensure comparability, flood safety levels for different rain events are defined, which have to be met in both scenarios. The environmental impacts are calculated for eight different categories, including climate change, resource depletion, eutrophication and acidification. The case study shows significantly lower impacts for the multi-functional, green infrastructure CMP, compared to the SSA. Among the installations, those measures which are installed to ensure no water on the surface during rain events with a return period of 10 years and handling small events with a return period of up to 0.2 years cause by far the largest share of the total environmental impacts in both scenarios (up to 96% for the CMP, and up to 84% for the SSA. In contrast, measures aimed at handling extreme events with a return period of up to 100 years only contribute up to 4% of the environmental impacts for the CMP and less than 1% for the SSA. Our method helps explain how the handling of everyday events and extreme rain events affect the environmental sustainability of climate change adaptation and it enables cities to consider the environmental sustainability of climate change adaptation solutions in the planning process.
Environmental performance of hydrothermal carbonization of four wet biomass waste streams at industry-relevant scales

Hydrothermal carbonization (HTC) of green waste, food waste, organic fraction of municipal solid waste (MSW), and digestate is assessed using life cycle assessment as a potential technology to treat biowaste. Water content of the biowaste and composition of the resulting hydrochar are important parameters influencing environmental performance. Hydrochar produced from green waste performs best and second best in respectively 2 and 10 out of 15 impact categories, including climate change, mainly due to low transportation needs of the biowaste and optimized pumping efficiency for the feedstock. By contrast, hydrochar produced from the organic fraction of MSW performs best in 6 impact categories, but has high potential impacts on human health and ecosystems caused by emissions of toxic elements through ash disposal. The greatest potential for environmental optimization for the HTC technology is in the use of heat and electricity with increasing plant size, but its overall environmental performance is largely influenced in a given geographic location by the incumbent waste management system that it replaces. Impact scores are within the range of existing alternative treatment options, suggesting that despite being relatively immature technology, and depending on the geographic location of the plant, HTC may be an attractive treatment option for biowaste.
Environmental Sustainability Assessment of Integrated Food and Bioenergy Production with Case Studies from Ghana

The use of agricultural residues for the production of bioenergy offers tantalising prospects of reduced pollution and greater food sovereignty. Integrated food and bioenergy systems seek to optimise the joint production of food and energy. Integrated food and bioenergy systems may be evaluated and compared with other food and energy systems using Environmental Sustainability Assessment (ESA).

This thesis investigates a range of integrated food and residue-based bioenergy production systems and provide methodological developments that are relevant for the assessment of such systems. The methodological developments concern distribution of environmental burden in multifunctional systems; consistent accounting of human labour inputs; and modelling of uncertainty regarding future conditions. Residue-based bioenergy relies on feedstock from production systems that are multifunctional, which means that they provide several outputs. Environmental impact assessment of residue-based bioenergy, therefore, involves the identification of relevant impacts occurring prior to the conversion of residues into bioenergy. Dividing the environmental burden of food production between food and crop residues to maintain a single-product focus is a contentious practice, since no obvious allocation factor is available. In evaluations of bioenergy production systems that are based on residues from food production, it is recommended to expand the assessment’s system perspective to include food production and food outputs. Human labour is an indispensable input in all agricultural and bioenergy production activities evaluated in ESA. Assessment methods, however, differ with respect to accounting for human labour inputs. Emergy Assessment (EmA) routinely includes human labour inputs, but based on a variety of calculation approaches. The collection of methods referred to as LCA (Life Cycle Assessment) methods usually disregard human labour as a relevant input. It is suggested to adhere to a systematic approach to estimating the environmental impact of human labour inputs that is applicable in EmA and other ESAs. I recommend that human labour be accounted in labour time, and that labour’s environmental impact be based on all inputs required for making labour available.

Practices and technologies that are expected to be implemented several decades into the future and that are compared with existing alternatives should not solely be compared using current conditions. The evaluation of these systems must take into consideration that future conditions may be significantly different from current conditions. It is suggested to use explorative scenarios based on narratives of the future to emphasise and be transparent about the uncertainty involved with planning for the medium to long-term. Modelling parameters may be deduced from such scenarios, making it possible to calculate scenario-dependent results. Applying the methodological developments above, two cases of integrated food and bioenergy production in Ghana are described. Crop residue-based biogas production and nutrient cycling in a remote village was shown to be a viable alternative to wood fuel and synthetic fertiliser use, in spite of increased labour inputs. In future scenarios where materials are scarce and labour plentiful, the investigated biogas-based and agroforestry technologies appear relatively more attractive. Fruit and cocoa residue-based biogas production in a fruit processing facility, with return of compost to pineapple farmers also proved to be a viable technology. It is recommended that relevant stakeholders explore the implementation of biogas and nutrient recycling technologies in preparation of reduced access to existing energy and nutrient sources. Primary contributions to the research field are suggested improvements to specific methods of evaluating integrated food and residue-based bioenergy systems. Evaluation of such systems requires an expanded system perspective that encompasses multiple outputs. It requires ways to properly account for labour, since energy and material input reductions, often associated with integration, result in increased labour inputs, as observed in the case studies. Evaluation also requires consideration of scenario uncertainty since implementation takes time and societal conditions may change significantly during the implementation phase. The contribution includes empirical data concerning farming and bioenergy conversion technologies in Ghana and a recommendation to implement biogas and nutrient recycling practices.

ErgoVSM: A Tool for Integrating Value Stream Mapping and Ergonomics in Manufacturing

Value stream mapping (VSM) is a lean tool aiming at waste reduction. Previous research suggests that the use of VSM may result in work intensification and thus an increased risk for the workers of developing work-related musculoskeletal disorders (MSD). In the current study, VSM was developed to also consider physical exposure in the analyzed production system (ErgoVSM). As the VSM, ErgoVSM is based on a participatory approach. ErgoVSM was tested in a Swedish manufacturing company. The results suggest that ErgoVSM catalyzes change processes to include intervention proposals emphasizing ergonomics in addition to waste reduction. Thus, ErgoVSM appeared useful for the investigated target group...
of production engineers and experienced operators. The performance improvements suggested when using the ordinary VSM seemed not to be hampered by adding the ergonomics complement. However, the use of ErgoVSM was somewhat more time consuming than the use of VSM. In conclusion, ErgoVSM is suggested as a feasible tool to be used by production engineers and experienced operators for including ergonomics considerations in the rationalization process. © 2015 Wiley Periodicals, Inc.
Essays on the Design of Contracts and Markets for Power System Flexibility

This PhD thesis consists of five essays on the economics of Power System Flexibility, a topic that has traditionally been addressed from a technical perspective by engineers, system planners, electricity industry stakeholders and energy policymakers interested in the integration of Variable Renewable Energy. While significant progress has been made in the understanding and characterization of exibility, its economic properties and the required incentives to provide it have not been sufficiently analyzed. The present work aims at filling this gap.

Estimating pesticide emission fractions for use in LCA: A global consensus-building effort

A practical challenge in LCA for comparing pesticide application in different agricultural practices is the agreement on how to quantify the amount emitted, while only the amount applied to the field is known. The main goal of this paper is to present an international effort carried out to reach agreement on recommended default agricultural pesticide emission fractions to environmental media. Consensual decisions on the assessment framework are:

1. Primary distributions are used as inputs for LCIA, while further investigating how to assess secondary emissions.
2. Framework and LCA application guidelines and documentation will be compiled.
3. The emission framework will be based on modifying PestLCI 2.0.
4. Drift values will be provided by German, Dutch, and other drift modelers.
5. Pesticide application methods will be complemented to develop scenarios for tropical regions.
6. Climate, soil, and application method scenarios will be based on sensitivity analysis.
7. Default emission estimates for LCA will be derived from production-weighted averages.
8. Emission fractions will be reported spatially disaggregated.

Recommendations for LCA practitioners and database developers are:

1. LCA studies should state whether the agricultural field belongs to technosphere or ecosphere.
2. Additional information needs to be reported in LCI (e.g., pesticide mass applied).
3. Emissions after primary distribution and secondary fate processes should be reported.
4. LCIA methods should allow for treating the field as part of technosphere and ecosphere.
5. Emission estimates derived from PestLCI 2.0 will be used in absence of detailed scenario data.
6. All assumptions should be reported.

The recommended pesticide emission fractions results and recommendations are presented and disseminated to strive for broad acceptance at a dedicated stakeholder workshop back-to-back with the current LCA Food 2016 conference in Dublin.

Estimating Preferences for Wind Turbine Locations - A Critical Review of Visualisation Approaches

As the amount of wind energy installed capacity keeps growing, in Europe and the world in general, the siting of wind projects near population or recreational centres becomes a frequent possibility. Therefore, it is of high interest for policymakers and developers to be able to quantify the effect of wind projects on public acceptance. Currently, one of the main drivers for acceptance of wind turbines by the public is their level of visual impacts. While recent studies have focused on estimating the welfare loss of visual impacts from wind turbines, a large share of the applied studies have used no or very simple visualisation of the actual visual impacts at stake. These studies thus rely on the cognitive skills of the respondents to imagine wind turbines of different sizes and locations; and on the prior experience people have had with wind turbines. By extending the economic model of perceived quality developed by Blomquist and Whitehead (1998), this paper provides...
a theoretical argument for the need of visualisations when describing valuation scenarios for respondents, as well as the relevance to correctly define the amount of attributes of the good to be represented on the visualisation, and which visualisation techniques to utilise. Afterwards, we propose a framework for classifying different visualisation types and utilise it to classify recent studies regarding wind turbines acceptance, highlighting the lack of visualisations in recent studies, as well as the need to raise the bar on scenario descriptions for wind turbine visual impacts valuation.

**Ethical aspects of life cycle assessments of diets**

Since the turn of the century a growing chorus of researchers has been espousing reduced meat and dairy intake as a partial strategy to transition towards a sustainable food system. Many of these studies have been predicated on a life-cycle assessment (LCA) methodology and though transparent in communicating their work within that framework, it has largely gone unmentioned that LCA involves a number of choices by the assessor and LCA methodology developers that are ultimately subjective. This study uses a consequential LCA of the average Danish diet in comparison to model vegetarian and vegan diets, leveraging the cultural perspectives afforded by the ReCiPe methodology, as starting point to explore the ways that subjectivity influences the LCA process and to test the robustness of the results against these different viewpoints. Mirroring earlier studies, we find vegetarian and vegan diets generally perform better environmentally compared to a standard Danish diet, but that there was minimal difference between the two no-meat options. Results were resilient to varying cultural perspectives applied in the model. LCA methodology, though loaded with value judgments, remains a dependable tool for assessing environmental dietary performance, but is less suited for estimating environmental pressures that are highly dependent on local conditions (e.g. chemical toxicity).

European mobility cultures: A survey-based cluster analysis across 28 European countries

More targeted European policies promoting green travel patterns require better knowledge on differing mobility cultures across European regions. As a basis for this, we clustered the EU population into eight mobility styles based on Eurobarometer data. The mobility styles - including, for example, "green cyclists" and "convenience drivers" - differed not only in their travel-related variables but also in their socio-economic background, IT-affinity, and life satisfaction, with green cyclist showing the highest life satisfaction and two car-oriented styles having the highest socio-economic resources. In a second step, the 28 EU member countries were clustered into six country clusters based on their representation of mobility styles. The country clusters indicate the existence of considerably different mobility cultures across the EU. Sub-regions can be identified that have highly different positions on the path towards sustainable mobility and therefore different requirements towards European platforms and support measures, e.g. for ‘Sustainable Urban Mobility Plans’. The country clusters can provide a starting point for future communication and targeting of European efforts in sustainable mobility.
Evaluating robustness of a diesel-degrading bacterial consortium isolated from contaminated soil

It is not known whether diesel-degrading bacterial communities are structurally and functionally robust when exposed to different hydrocarbon types. Here, we exposed a diesel-degrading consortium to model either alkanes, cycloalkanes or aromatic hydrocarbons as carbon sources to study its structural resistance. The structural resistance was low, with changes in relative abundances of up to four orders of magnitude, depending on hydrocarbon type and bacterial taxon. This low resistance is explained by the presence of hydrocarbon-degrading specialists in the consortium and differences in growth kinetics on individual hydrocarbons. However, despite this low resistance, structural and functional resilience were high, as verified by re-exposing the hydrocarbon-perturbed consortium to diesel fuel. The high resilience is either due to the short exposure time, insufficient for permanent changes in consortium structure and function, or the ability of some consortium members to be maintained during exposure on degradation intermediates produced by other members. Thus, the consortium is expected to cope with short-term exposures to narrow carbon feeds, while maintaining its structural and functional integrity, which remains an advantage over biodegradation approaches using single species cultures.

Evolvable Smartphone-Based Point-of-Care Systems For In-Vitro Diagnostics

Recent developments in the life-science -omics disciplines, together with advances in micro- and nanoscale technologies offer unprecedented opportunities to tackle some of the major healthcare challenges of our time. Lab-on-Chip technologies coupled with smart-devices in particular, constitute key enablers for the decentralization of many in-vitro medical diagnostics applications to the point-of-care, supporting the advent of a preventive and personalized medicine. Although the technical feasibility and the potential of Lab-on-Chip/smart-device systems is repeatedly demonstrated, direct-to-consumer applications remain scarce. This thesis addresses this limitation. After identifying system evolvability as a key enabler to the adoption and long-lasting success of next-generation point-of-care systems by favoring the integration of new technologies, streamlining the reengineering efforts for system upgrades and limiting the risk of premature system obsolescence. Among possible strategies, platform-based design represents a particularly suitable entry point to the development of evolvable systems. One necessary condition, is for change-absorbing and change-enabling mechanisms to be incorporated in the platform architecture at initial design-time. Important considerations arise as to where in Lab-on-Chip/smart-device platforms can these mechanisms be integrated, and how to implement them.

Our investigation revolves around the silicon-nanowire biological field effect transistor, a promising biosensing technology for the detection of biological analytes at ultra low concentrations. We discuss extensively the sensitivity and instrumentation requirements set by the technology before we present the design and implementation of an evolvable smartphone-based platform capable of interfacing lab-on-chips embedding such sensors. We elaborate on the implementation of various architectural patterns throughout the platform and present how these facilitated the evolution of the system towards one accommodating for electrochemical sensing. Model-based development was undertaken throughout the engineering process. A formal SysML system model fed our evolvability assessment process. We introduce, in particular, a model-based methodology enabling the evaluation of modular scalability: the ability of a system to scale the current value of one of its specification by successively reengineering targeted system modules. The research work presented in this thesis provides a roadmap for the development of evolvable point-of-care systems, including those targeting direct-to-consumer applications. It extends from the early identification of anticipated change, to the assessment of the ability of a system to accommodate for these changes. Our research should thus interest industrials eager not only to disrupt, but also to last in a shifting socio-technical paradigm.
Experience with Grid Expansion in a Northern European Perspective
The power grid constitutes an essential flexibility option for integrating ever-greater shares of variable renewable energy, such as wind power and solar photovoltaics. The development of interconnectors between neighboring EU Member States enables cross-border balancing. The potential for trade results from the differences in hourly wholesale electricity prices between regions or countries. The presentation given by Stephanie Ropenus at the 4. BNetzA Meets Science Dialogue provides some insights into increased integration of European electricity markets from a Nordic-German perspective. In doing so, it draws on the results of three reports commissioned by Agora Energiewende where Stephanie Ropenus acted as project leader, [1], [14] and [15], or co-author [2]. Increased integration between the Nordic countries and Germany will become ever more important as the share of renewables increases. Denmark is a prime example of how great interconnectivity can enable the integration of high wind energy shares into the power system. To some extent the Nordic electricity system can be considered unique with its complimentary power generation mix of wind energy in Denmark and hydropower as a "green battery" in Norway and Sweden. In general, closer integration of the Nordic and German power systems leads to better utilization of renewable energy and induces price convergence between the two regions on the wholesale electricity market. While the overall welfare effects of increased integration are positive, there may be significant distributional effects across stakeholder groups (power producers and consumers) within countries. These effects need to be taken into account for creating public acceptance for new lines and for the cross-border allocation of network investments.

Experimental Design Research: Approaches, Perspectives, Applications
This book presents a new, multidisciplinary perspective on and paradigm for integrative experimental design research. It addresses various perspectives on methods, analysis and overall research approach, and how they can be synthesized to advance understanding of design. It explores the foundations of experimental approaches and their utility in this domain, and brings together analytical approaches to promote an integrated understanding. The book also investigates where these approaches lead to and how they link design research more fully with other disciplines (e.g. psychology, cognition, sociology, computer science, management). Above all, the book emphasizes the integrative nature of design research in terms of the methods, theories, and units of study—from the individual to the organizational level. Although this approach offers many advantages, it has inherently led to a situation in current research practice where methods are diverging and integration between individual, team and organizational understanding is becoming increasingly tenuous, calling for a multidisciplinary and transdisciplinary perspective. Experimental design research thus offers a powerful tool and platform for resolving these challenges. Providing an invaluable resource for the design research community, this book paves the way for the next generation of researchers in the field by bridging methods and methodology. As such, it will especially benefit postgraduate students and researchers in design research, as well as engineering designers.

Experimental investigations on heat content of supercooled sodium acetate trihydrate by a simple heat loss method

Sodium acetate trihydrate is a phase change material that can be used for long term heat storage in solar heating systems because of its relatively high heat of fusion, a melting temperature of 58 °C and its ability to supercool stable. In practical applications sodium acetate trihydrate tend to suffer from phase separation which is the phenomenon where anhydrous salt settles to the bottom over time. This happens especially in supercooled state. The heat released from the crystallization of supercooled sodium acetate trihydrate with phase separation will be lower than the heat released from sodium acetate trihydrate without phase separation. Possible ways of avoiding or reducing the problem of phase separation were investigated. A wide variety of composites of sodium acetate trihydrate with additives including extra water, thickening agents, solid and liquid polymers have been experimentally investigated by a simple heat loss method.

The aim was to find compositions of maximum heat released from the crystallization of supercooled sodium acetate trihydrate samples at ambient temperature. It was found that samples of sodium acetate trihydrate with 0.5–2% (wt.%) Carboxy-Methyl Cellulose, 0.3–0.5 % (wt.%) Xanthan Gum or 1–2% (wt.%) of some solid or liquid polymers as additives had significantly higher heat contents compared to samples of sodium acetate trihydrate suffering from phase separation.
Exploration of the Barriers to Implementing Different Types of Sustainability Approaches

Integrating sustainability into business is gaining increased attention. Yet, implementing long-lasting sustainability approaches remains a complex task. Many empirical studies have identified the barriers to such implementation but the variation in challenges faced by companies, depending on the focus of the approach being implemented, is not addressed. The aim of this paper is i) to explore the barriers related to implementing different types of sustainability approaches and ii) to look for indications of similarities and differences across types of approaches. The research builds on data about the barriers, collected from a sample of twenty-two empirical studies in academic research and additional reports. The findings show that performance measurement systems and access to industry-specific information, benchmark or reference cases are common areas of difficulty across all types. The main variation is an increase in barriers beyond the company's boundaries, when shifting from a production to a value proposition focus. The results are limited by the unbalanced distribution of studies and the variety in methodologies present in the sample. Further research on barrier identification, prioritization and influential parameters is recommended.
Exploring Human Capital and Hybrid Entrepreneurship

An individual’s human capital affects their choice to become an entrepreneur and also their likely success as a nascent entrepreneur. This paper explores how hybrid employment—entrepreneur opportunities impact these dynamics. Drawing on insights from decision theory, we argue that an individual’s human capital influences entrepreneurial pursuits as a two stage process, first shaping whether nascent entrepreneurship and/or employment enters an individual’s consideration set when they are facing a career transition and second influencing the outcomes of entrepreneurial pursuits. Using a novel longitudinal dataset of individuals facing career transition as nascent entrepreneurs, job seekers or both, we find that while hybrid nascent entrepreneurship (trying to start a business while being employed) has a positive influence on outcomes, hybrid search (concurrent job search while trying to start a business) has a strong negative influence.

Exposure to chemicals in consumer products: The role of the near-field environment

Humans can be exposed to chemicals in consumer products during product use and environmental releases with inhalation, ingestion, and dermal uptake as typical exposure routes. Nevertheless, chemical exposure modeling has traditionally focused on the far-field with near-field indoor models only recently gaining attention. Further, models that are mostly emissions-based, may not necessarily be applicable to all types of chemical release from consumer products. To address this gap, we (1) define a framework to simultaneously account for exposure to chemicals in the near- and far-field, (2) determine chemical product concentrations for various functional use categories, (3) introduce a quantitative metric linking exposure to chemical mass in products, the Product Intake Fraction (PiF), and (4) demonstrate our framework for various consumer product categories. This framework lends itself to high-throughput calculations for characterizing exposure to the vast consumer product chemical space. The chemical mass in products is used as a starting point for quantifying human exposure obtained by multiplying the chemical concentration (e.g. % w/w) in the product with the amount of product used per defined application. Chemical concentrations in products can be obtained from empirical studies, formulations and associations described in databases, or when unavailable, estimated based on chemical-product functions or regulatory frame formulations. Exposure is quantified by estimating the PiF, the fraction of the chemical in a product that is taken in by humans via each exposure pathway, considering specific compartments of entry into the near-field environment (releases of chemicals encapsulated in articles, indoor air spray, etc.). To estimate PiFs, we combined far-field environmental compartments with near-field compartments and exposure pathways in a multimedia matrix of transfer fractions, with columns and rows for each compartment and exposure pathway. The multiple transfers and PiFs (e.g. from chemicals encapsulated in articles to inhalation of indoor air and dermal uptake via skin contact) were obtained by inverting the transfer fractions matrix, yielding cumulative multimedia transfer fractions. PiFs for various chemicals in products were found to be on the order of 1x10^-7 for semi-volatile organic compounds (SVOCs) in thick flooring, 5x10^-3 for VOCs in indoor air spray, and up to 95% or even higher for ingredients in leave-on cosmetic products.
Exposure to chemicals in food packaging as a sustainability trade-off in LCA

Hazardous chemicals in packaging, including 'eco-friendly' and recycled food packaging, can migrate into food and expose humans. LCA has been fundamental to indicate more 'eco-friendly' packages, but currently LCA does not consider exposure to chemical migrants and methods have not yet been developed. In this study we question if exposure to chemicals in food packaging should be considered as a sustainable design consideration, i.e. if this human health risk is relevant in a life cycle context. To answer this question, we focus on developing methods to quantify exposure to chemicals in food packaging in a life cycle impact assessment (LCIA) framework. To put exposure during use in a life cycle context we perform a screening-level LCA of several life cycle stages of high impact polystyrene packaging (HIPS), with a functional unit of containing and delivering one kilogram of yogurt for consumption. For screening, we include exposure via environmental emissions from the production of the raw material HIPS, thermoforming into packaging, 14 day refrigeration by consumers, and disposal via incineration. The purpose of this screening is not to obtain a detailed and accurate LCA of HIPS but to provide life cycle context to compare the magnitude of characterized exposure to chemicals in packaging, in order to elucidate if this exposure pathway is important. We detail estimates of life cycle exposure to one known hazardous chemical in polystyrene packaging (styrene) that has data available on concentrations in yogurt packaged in HIPS and life cycle inventory releases. We also extend this analysis, given data limitations, to include exposure to three other chemicals in HIPS packaging through food. Given that data on concentrations of food packaging chemicals in food are often missing, we also explore methods to model the product intake fraction (PiF) as the fraction of chemical mass taken in through food packaging versus its initial mass in the food packaging. Results demonstrated that in the given cases consumer exposure to chemicals in packaging through consuming packaged food can be greater than population-level exposure mediated by the life cycle releases of such chemicals, even when only considering one or several chemicals in packaging that expose consumers. Occupational exposure was not considered in this study, but could be a focus of future work.

Thus, this initial exploration indicates that exposure to chemicals in food packaging can be an essential consideration for burden shifting and quantifying design trade-offs in a life cycle context.

Extension of internationalisation models drivers and processes for the globalisation of product development: a comparison of Danish and Chinese engineering firms

This paper develops an extension to established production- and supply chain management focused internationalisation models. It applies explorative case studies in Danish and Chinese engineering firms to discover how the globalisation process of product development differs from Danish and Chinese perspectives. The paper uses internationalisation and global product development theory to explain similarities and differences in the approaches. Grounded in case study results, a new model for internationalisation is proposed. The new model expands the internationalisation process model to include steps of product development and collaborative distributed development beyond sourcing, sales and production elements. The paper then provides propositions for how to further develop the suggested model, and how western companies can learn from the Chinese approaches, and globalise their product development activities from the front end of the value chain rather than from the back-end.
Facilities Management and Corporate Real Estate Management as Value Drivers: How to Manage and Measure Adding Value.

Facilities Management (FM) and Corporate Real Estate Management (CREM) are two closely related and relatively new management disciplines with developing international professions and increasing academic attention. Both disciplines have from the outset a strong focus on controlling and reducing cost for real estate, facilities and related services. In recent years there has been a change towards putting more focus on how FM/CREM can add value to the organisation.

The book is research based with a focus on guidance to practice. It offers a transdisciplinary approach, integrating academic knowledge from a variety of different fields with practical experience. It also includes 12 interviews with practitioners, shedding light as to how they manage adding value in practice.

This is a much needed resource for practitioners, researchers and teachers from the field of FM and CREM, as well as students at both undergraduate and postgraduate level.

Factors contributing to young moped rider accidents in Denmark

Young road users still constitute a high-risk group with regard to road traffic accidents. The crash rate of a moped is four times greater than that of a motorcycle, and the likelihood of being injured in a road traffic accident is 10-20 times higher among moped riders compared to car drivers. Nevertheless, research on the behaviour and accident involvement of young moped riders remains sparse. Based on analysis of 128 accident protocols, the purpose of this study was to increase knowledge about moped accidents. The study was performed in Denmark involving riders aged 16 or 17. A distinction was made between accident factors related to (1) the road and its surroundings, (2) the vehicle, and (3) the reported behaviour and condition of the road user. Thirteen accident factors were identified with the majority concerning the reported behaviour and condition of the road user. The average number of accident factors assigned per accident was 2.7. Riding speed was assigned in 45% of the accidents which made it the most frequently assigned factor on the part of the moped rider followed by attention errors (42%), a tuned up moped (29%) and position on the road (14%). For the other parties involved, attention error (52%) was the most frequently assigned accident factor. The majority (78%) of the accidents involved road rule breaching on the part of the moped rider. The results indicate that preventive measures should aim to eliminate violations and increase anticipatory skills among moped riders and awareness of mopeds among other road users. Due to their young age the effect of such measures could be enhanced by infrastructural measures facilitating safe interaction between mopeds and other road users.

Fatal and serious road crashes involving young New Zealand drivers: a latent class clustering approach

The over-representation of young drivers in road crashes remains an important concern worldwide. Cluster analysis has been applied to young driver sub-groups, but its application by analysing crash occurrence is just emerging. We present a classification analysis that advances the field through a holistic overview of crash patterns useful for designing youth-targeted road safety programmes. We compiled a database of 8644 New Zealand crashes from 2002 to 2011 involving at least one 15–24-year-old driver and a fatal or serious injury for at least one road user. We considered crash location, infrastructure characteristics, environmental conditions, demographic characteristics, driving behaviour, and pre-crash manoeuvres. The analysis yielded 15 and 8 latent classes of, respectively, single-vehicle and multi-vehicle crashes, and average posterior probabilities measured the odds of correct classification that revealed how the identified clusters contain mostly crashes of a particular class and all the crashes of that class. The results raised three major safety concerns for young drivers that should be addressed: (1) reckless driving and traffic law violations; (2) inattention, error, and hazard perception problems; and (3) interaction with road geometry and lighting conditions, especially on high-speed open roads and state highways.

Feasibility Study on HYSOL CSP

Concentrating Solar Power (CSP) plants utilize thermal conversion of direct solar irradiation. A trough or tower configuration focuses solar radiation and heats up oil or molten salt that subsequently in high temperature heat exchangers generate steam for power generation. High temperature molten salt can be stored and the stored heat can thus increase the load factor and the usability for a CSP plant, e.g. to cover evening peak demand. In the HYSOL concept (HYbrid SOLar) such configuration is extended further to include a gas turbine fuelled by upgraded biogas or natural gas. The optimised integrated HYSOL concept, therefore, becomes a fully dispatchable (offering firm power) and fully renewable energy source (RES) based power supply alternative, offering CO2-free electricity in regions with sufficient solar resources. The economic feasibility of HYSOL configurations is addressed in this paper. The CO2 free HYSOL alternative is discussed relative to conventional reference firm power generation technologies. In particular the HYSOL performance relative to new power plants based on natural gas (NG) such as open cycle or combined cycle gas turbines (OCGT or CCGT) are in focus. The feasibility of renewable based HYSOL power plant configurations attuned to specific electricity consumption patterns in selected regions with promising solar energy potentials are discussed.

Feature selection for portfolio optimization

Most portfolio selection rules based on the sample mean and covariance matrix perform poorly out-of-sample. Moreover, there is a growing body of evidence that such optimization rules are not able to beat simple rules of thumb, such as 1/N. Parameter uncertainty has been identified as one major reason for these findings. A strand of literature addresses this problem by improving the parameter estimation and/or by relying on more robust portfolio selection methods. Independent of the chosen portfolio selection rule, we propose using feature selection first in order to reduce the asset menu. While most of the diversification benefits are preserved, the parameter estimation problem is alleviated. We conduct out-of-sample back-tests to show that in most cases different well-established portfolio selection rules applied on the reduced asset universe are able to improve alpha relative to different prominent factor models.

Finding equidistant nondominated points for biobjective mixed integer programs

The nondominated frontier of a multiobjective optimization problem can be overwhelming to a decision maker, as it is often either exponential or infinite in size. Instead, a representation of this set in the form of a small sample of points is often preferred. In this paper we present a new biobjective criterion space search method for generating a small set of equidistant points based on the space division idea behind Voronoi diagrams. The motivation for this method stems from the finding that there exists a dual relationship between the well-established quality measures of coverage and uniformity, and that a set of equidistant points closes the gap. The method is easy to implement, and relies only on the availability of a black-box solver. We show on a benchmark set of biobjective mixed integer programming instances that the method outperforms the state of the art with respect to both coverage and uniformity.
Fodgængervenlige fronter
Risikoen for personskade er stor, når en fodgænger rammes af en bil. Fodgængervenlige fronter anses for at være en måde at bidrage til mindre tilskadekomst blandt fodgængere i trafikken. Denne undersøgelses resultater tyder på, at fodgængervenlige fronter under visse betingelser kan reducere risikoen for at fodgængere får varige mén i forbindelse med et færdselsuheld.

Foresight and the third mission of universities: the case for innovation system foresight

Purpose – This paper aims to argue that innovation system foresight (ISF) can significantly contribute to the third mission of universities by creating an active dialogue between universities, industry and society.

Design/methodology/approach – This paper’s approach is conceptual. The authors analyse the third mission and relevant literature on innovation systems and foresight to explain how and why foresight contributes to the third mission.

Findings – The authors propose that foresight contributes to the third mission of universities, particularly to the research and development and innovation dimensions through the development of joint understanding of the agendas and future needs of stakeholders. In addition, foresight enables education to be designed to address identified needs.

Research limitations/implications – The findings are both conceptual and exploratory in nature. Thus, the argument needs further examination through a broader study on foresight in the university–industry context and/or longitudinal research on the outcomes and impact of foresight in this context.

Practical implications – The findings highlight the importance of understanding the systemic nature of innovation and its role in economic development. Universities must understand their role within the larger innovation system to fulfil the potential of economic development and by extension, their third mission.

Originality/value – The paper outlines a novel approach of using ISF to promote university–industry partnerships and the growth of innovation systems. The paper also contributes to the discussion of the third mission by outlining that mission in practical terms.
We propose that foresight can contribute to inclusive development by making innovation policy processes more inclusive, which in turn makes innovation systems more inclusive. Processes of developing future-oriented innovation policies are often unsuccessful and rarely inclusive. We conceptualize such processes as foresighting. We focus on how the ex-ante design of policymaking processes affects the actual process with a focus on inclusion, and we discuss how it affects policy effectiveness and innovation system transformation. Our argument is that processes of policymaking must be inclusive to affect and transform innovation systems because a set of distributed actors, rather than ministries and innovation agencies, is the gatekeepers of change. From this perspective, inclusion is a precondition rather than an obstacle for transformation. We develop a conceptual framework and use it to study design and processes in two foresight cases in two emerging economies - Brazil and South Korea. Although the research is exploratory and the results tentative, the empirical studies support our main propositions.
Der er et stigende behov for viden om, hvordan vi prioriterer forbedringer af vejnettet med et særligt fokus på de investeringer som gavner trafiksikkerheden. Denne prioriteringsliste skal findes via et nyt forskningsprojekt støttet af Asfaltindustrien. Her sættes der fokus på samfundsøkonomiske analyser baseret på nye trafikuheldsmodeller som tager højde for vejens tilstand.

Framework for Multi-Pathway Cumulative Exposure for Comparative Assessments

Efforts to assess human and ecosystem exposure to contaminants released to multiple environmental media have been evolving over the last decades. In this talk, we summarize the development and evolution of the multimedia mass-balance approach combined with multi-pathway exposure assessment as a framework for comparative assessment of chemicals, products, and services. We first review the development and evolution of the multimedia mass-balance approach to pollutant fate and exposure evaluation and illustrate some of the calculations used in multimedia, multi-pathway exposure assessments. The multimedia approach requires comprehensive assessments that locate all points of chemical release to the environment, characterize mass-balance relationships, and track contaminants through the entire environmental system to exposure of individuals or populations or specific ecosystems. For use in comparative risk assessment, life-cycle assessment (LCA), and chemical alternatives assessment (CAA), multimedia fate and exposure models synthesize information about partitioning, reaction, and intermedia-transport properties of chemicals in a representative (local to regional) or generic (continental to global) environment with information about larger scale populations rather than specific individuals or vulnerable subgroups. Although there can be large uncertainties in this approach, it provides insight on how chemical properties and use patterns map onto population-scale metrics of exposure, such as intake fraction for characterizing human intake per unit emission and aquatic or terrestrial ecosystem exposure concentrations per unit emission. We next discuss the reliability with which fate models at different levels of geographic scale—from near field indoor scales to urban, regional, continental and even global scale—can be used to determine cumulative human exposure and/or ecosystem exposure from multiple pollutants and emissions sources. The key question here is whether the results of cumulative assessments can provide sufficient insight for decision makers who are concerned with life-cycle impacts and chemical alternatives. We present a regional case study for pesticide alternatives in an agricultural valley of California to assess the opportunities and future prospects for the multi-pathway cumulative framework in LCA and CAA. This case reveals that the relative contributions to cumulative pollutant intake via different exposure pathways depend on (a) persistence of chemicals at different levels of integration (regional, urban-scale, food-web, indoors), (b) basic chemical properties, (c) the retention of chemicals in food webs, and (d) the retention of chemicals by indoor surfaces.

From employee representation to problem-solving: Mainstreaming OHS management

The role of occupational health and safety representatives is changing. A study in 60 Danish enterprises indicates that representation, and especially negotiation on behalf of colleagues, has diminished. The work environment is mainstreamed in many enterprises and is rarely an area of conflict. The role of OHS representatives has accordingly changed to focus on solving specific problems in the workplace as an integrated part of daily operations. Both management and colleagues consider the OHS representatives as a resource that can be utilized to manage the work environment. The consequences of this development for the employees may be a stronger joint management–employee effort to improve the work environment, but also management domination and an accordingly weaker employee voice in some companies.

From university research to innovation: Detecting knowledge transfer via text mining

Knowledge transfer by universities is a top priority in innovation policy and a primary purpose for public research funding, due to being an important driver of technical change and innovation. Current empirical research on the impact of university research relies mainly on formal databases and indicators such as patents, collaborative publications and license agreements, to assess the contribution to the socioeconomic surrounding of universities. In this study, we present an extension of the current empirical framework by applying new computational methods, namely text mining and pattern recognition. Text samples for this purpose can include files containing social media contents, company websites and annual reports. The empirical focus in the present study is on the technical sciences and in particular on the case of the Technical University of Denmark (DTU). We generated two independent text collections (corpora) to identify correlations of university publications and company webpages. One corpus representing the company sites, serving as sample of the private economy and a second corpus, providing the reference to the university research, containing relevant publications. We associated the former with the latter to obtain insights into possible text and semantic relatedness. The text mining methods are extrapolating the correlations, semantic patterns and content comparison of the two corpora to define the document relatedness. We expect the development of a novel tool using contemporary techniques for the measurement of public research impact. The approach aims to be applicable across universities and thus enable a more holistic comparable assessment. This rely less on formal databases, which is certainly beneficial in terms of the data reliability. We seek to provide a supplementary perspective for the detection of the dissemination of university research and hereby enable policy makers to gain additional insights of (informal) contributions of knowledge dissemination by universities.

From Visions of Grandeur to Grand Failure: Alternative schools of descriptive decision theories to explain the Berlin Brandenburg
Berlin Brandenburg Airport exemplifies the impact of poor decisions in projects. Extant research on behavioural decision making in project contexts offers a variety of explanations for poor decisions. However, the research sheds only spotlights on the field. It could benefit from a stronger coverage of theories in cognitive and social psychology and integration of findings and concepts across theoretical traditions. Drawing on the developments of Behavioural Strategy, this paper proposes the concept of ‘Behavioural Projects’ as a host of the growing body of research on behavioural decision making in projects. We organise extant research in a conceptual framework rooted in three schools of thinking - psychological (reductionist), political (pluralist) and social (contextualist). We illustrate how the three schools and their integration provide ample research opportunities through an analysis of decisions in the Berlin Brandenburg Airport fiasco. Based on our framework, we propose a research program that serves as inspiration for future studies on the crossroads between cognitive and social psychology theories and decision situations in projects. We hope that such future research will give rise to the development of an integrated behavioural decision making theories for temporary organisations.

Full-shipload tramp ship routing and scheduling with variable speeds

This paper investigates the simultaneous optimization problem of routing and sailing speed in the context of full-shipload tramp shipping. In this problem, a set of cargoes can be transported from their load to discharge ports by a fleet of heterogeneous ships of different speed ranges and load-dependent fuel consumption. The objective is to determine which orders to serve and to find the optimal route for each ship and the optimal sailing speed on each leg of the route so that the total profit is maximized. The problem originated from a real-life challenge faced by a Danish tramp shipping company in the tanker business. To solve the problem, a three-index mixed integer linear programming formulation as well as a set packing formulation is presented. A novel Branch-and-Price algorithm with efficient data preprocessing and heuristic column generation is proposed. The computational results on the test instances generated from real-life data show that the heuristic provides optimal solutions for small test instances and near-optimal solutions for larger test instances in a short running time. The effects of speed optimization and the sensitivity of the solutions to the fuel price change are analyzed. It is shown that speed optimization can improve the total profit by 16% on average and the fuel price has a significant effect on the average sailing speed and total profit.

Purpose: The static functional unit definition in the current LCA framework has limitations in addressing the changing product functionality and associated environmental impact of constantly evolving product technologies. As a result, it overlooks the changes in consumer behaviour of increased consumption of products in provided services as well as in growing volumes. This article aims to present a new framework in defining a dynamic functional unit of product technologies that caters for changes in consumer behaviour and growing market. Methods: A new approach to defining the functional unit is proposed that caters for changes in consumer behaviour and the use of technology from a technical performance perspective. A dynamic approach to definition of the functional unit is proposed that is based on Kano’s model of product function and satisfaction. Results and discussion: The new approach is demonstrated on a case study in which the analysis of historical data for two TV product technologies—CRT and LCD—is used to show how the total environmental impact is increasing due to the increased functionality which triggers an increase in the volume of the
market. Despite the efforts of improving product life cycle design, the society is still faced with increasing environmental impact from the product type overall. Conclusions: This article presents the challenges of using a static, single functional unit definition in an industrial culture with constant evolution of products that influences usage behaviour and demonstrates the vicious circle of improving product efficiency that leads to further consumption and environmental impact. To address this problem, a new framework of dynamic functional unit definition is put forward for performing comparative LCA to manage the development of product life cycle design that helps keep the total environmental impact of the company’s product portfolio within absolute boundaries.

Gender bias in academic recruitment

It is well known that women are underrepresented in the academic systems of many countries. Gender discrimination is one of the factors that could contribute to this phenomenon. This study considers a recent national academic recruitment campaign in Italy, examining whether women are subject to more or less bias than men. The findings show that no gender-related differences occur among the candidates who benefit from positive bias, while among those candidates affected by negative bias, the incidence of women is lower than that of men. Among the factors that determine success in a competition for an academic position, the number of the applicant’s career years in the same university as the committee members assumes greater weight for male candidates than for females. Being of the same gender as the committee president is also a factor that assumes greater weight for male applicants. On the other hand, for female applicants, the presence of a full professor in the same university with the same family name as the candidate assumes greater weight than for male candidates.

Gender differences in customer expectations and perceptions of corporate social responsibility

The literature on business ethics, corporate social responsibility and sustainability includes many studies on gender differences, however the results are often contrasting. In particular, there has not yet been full agreement on the role and significance of gender differences in customer expectations and perceptions of responsible corporate conduct. An extensive review of the research on the subject reveals that the published studies have not dealt with the substantive significance of gender differences, and as a result, the size of such differences is unknown. The current study analyses both the statistical and the substantive significance of gender differences in customer expectations and perceptions of corporate social responsibility, also examining the influence of age and education. The analysis is carried out on a remarkably large sample of 908 clients, pertaining to 12 of the largest Italian banks. The overall results show that there is a small substantive difference between women’s and men’s average expectations, with women showing higher average values than men. This result holds generally true with variation of education levels and age groups. Young females show the highest average values of expectations, and the significance of gender differences decreases with age. In contrast, the perception of corporate social responsibility does not show significant gender differences, either at the general level or when the analyses are repeated by education levels and age groups. The paper introduces the use of a standardized measure of effect size for analysing the substantive significance of gender differences in customer expectations and perceptions of corporate social responsibility. This novel approach increases results reliability and, accordingly, the effectiveness of company or policy maker strategies in designing, planning, implementing and assessing sustainability initiatives.

Generation of safe optimised execution strategies for UML models

When designing safety critical systems there is a need for verification of safety properties while ensuring system operations have a specific performance profile. We present a novel application of model checking to derive execution strategies, sequences of decisions at workflow branch points, for a fragment of the Unified Modelling Language (UML) statechart language which is extended to include modelling of workflows which exhibit stochastic behaviour. Strategy generation is made possible by performing model checking on specific permutations of the set of possible actions to generate adversaries which optimise a set of reward variables, while simultaneously observing constraints which encode any required safety properties and accounting for the underlying stochastic nature of the system. By evaluating quantitative properties of the generated adversaries we are able to construct an execution strategy which fully specifies, from any state in the system, the actions needed for an actor to achieve the optimal values of the quantitative goals. We show that our method is computationally feasible and apply it to an illustrative example featuring an industrial robot in the food industry. Our approach make it possible to readily test and debug a wide range of possible designs, thus creating a more effective development of a safety critical system.

Getting the chemicals right: addressing inorganics in sustainability assessments of technologies

A main goal of sustainability research is to enable a technological development in industry and elsewhere that ensures that what is produced and how it is produced today does not harm the quality of human or environmental health for present and future generations. As part of current environmental sustainability assessments, the toxicity potential of several thousand organic chemicals is included in characterization models within life cycle impact assessment (LCIA). However, many economic production processes involve the use of inorganic chemicals to a large extent, while the related pressure on human and environmental health of environmental emissions of these substances is not yet fully understood and not included in any existing LCIA method. In this presentation, we provide an overview of the relevance of inorganic chemicals and outline possible ways towards incorporating inorganic chemicals in LCIA toxicity characterization.

Global guidance on environmental life cycle impact assessment indicators: Progress and case study

Purpose

The life cycle impact assessment (LCIA) guidance flagship project of the United Nations Environment Programme (UNEP)/Society of Environmental Toxicology and Chemistry (SETAC) Life Cycle Initiative aims at providing global guidance and building scientific consensus on environmental LCIA indicators. This paper presents the progress made since 2013, preliminary results obtained for each impact category and the description of a rice life cycle assessment (LCA) case study designed to test and compare LCIA indicators.

Methods

The effort has been focused in a first stage on impacts of global warming, fine particulate matter emissions, water use and land use, plus cross-cutting issues and LCA-based footprints. The paper reports the process and progress and specific results obtained in the different task forces (TFs). Additionally, a rice LCA case study common to all TF has been developed. Three distinctly different scenarios of producing and cooking rice have been defined and underlined with life cycle inventory data. These LCAs help testing impact category indicators which are being developed and/or selected in the harmonisation process. The rice LCA case study further helps to ensure the practicality of the finally recommended impact category indicators.

Results and discussion

The global warming TF concludes that analysts should explore the sensitivity of LCA results to metrics other than GWP. The particulate matter TF attained initial guidance of how to include health effects from PM$_{2.5}$ exposures consistently into LCIA. The biodiversity impacts of land use TF suggests to consider complementary metrics besides species richness for assessing biodiversity loss. The water use TF is evaluating two stress-based metrics, AWaRe and an alternative indicator by a stakeholder consultation. The cross-cutting issues TF agreed upon maintaining disability-adjusted life years (DALY) as endpoint unit for the safeguard subject “human health”. The footprint TF defined main attributes that should characterise all footprint indicators. "Rice cultivation" and “cooking” stages of the rice LCA case study contribute most to the environmental impacts assessed.

Conclusions

The results of the TF will be documented in white papers and some published in scientific journals. These white papers represent the input for the Pellston workshop ™, taking place in Valencia, Spain, from 24 to 29 January 2016, where best practice, harmonised LCIA indicators and an update on the general LCIA framework will be discussed and agreed on. With the diversity in results and the multi-tier supply chains, the rice LCA case study is well suited to test candidate recommended indicators and to ensure their applicability in common LCA case studies.
Global product development: KPI selection support

Selecting key performance indicators in conventional product development is a challenging task for project management and is compound by global product development. Informed from the findings of two in depth case studies conducted with large Danish manufacturing companies, in this paper we develop and test a framework that supports the selection of Leading and Lagging key performance indicators in global product development. The framework provides an alternative approach to design, select and document key performance indicators by incorporating a challenge-oriented approach to selection.

Green corridors and network design
The purpose of this chapter is to investigate the relation between the Trans-European Transport Network (TEN-T) and the green corridor concept. First, the need is established for a corridor governance structure that enables the close cooperation among the numerous stakeholders from both the public and private sectors engaged in all corridor related issues ranging from network design to the provision of integrated logistical solutions. The governance scheme of the recently introduced TEN-T core network corridors seems to fulfil this requirement. Following a brief history of TEN-T development, the 2013 major overhaul of the EU transportation infrastructure policy is outlined and the basic differences with the past are pinpointed. The provisions of the new TEN-T Guidelines are scrutinized so as to check whether the TEN-T core network corridors exhibit the characteristics of a green corridor, as they have been identified in the previous chapter. Based on the results of this analysis, it is concluded that the TEN-T core network is, as far as its freight dimension is concerned, a network of green corridors.

Green corridors basics
The purpose of this chapter is to introduce the concept of ‘green corridors’ as a means to develop integrated, efficient and environmentally friendly transportation of freight between major hubs and by relative long distances. The basis of this material is work conducted in the context of the EU SuperGreen project, which aimed at advancing the green corridor concept through a benchmarking exercise involving Key Performance Indicators (KPIs). The chapter discusses the available definitions of green corridors and identifies the characteristics that distinguish a green corridor from any other efficient surface transportation corridor. After providing examples of green corridor projects in Europe, it focuses on the KPIs that have been proposed by various projects for monitoring the performance of a freight corridor. Emphasis is given to the SuperGreen KPIs, covering the economic, technical, environmental, social and spatial planning aspects of freight logistics, as they have been scrutinized extensively by stakeholders in order to keep their number within practical and operable limits. In addition, the chapter presents the performance monitoring methodology that was developed by SuperGreen in an effort to close the gap of earlier works. The lessons learned from SuperGreen lead to a revised methodology suitable for monitoring the performance of a corridor.

Authors: Panagakos, G. (Intern)
The subject of this thesis is ‘green corridors,’ a European concept denoting a concentration of freight traffic between major hubs and by relatively long distances. Since their inception in 2007, green corridors have gained popularity as a policy tool that enhances the overall environmental sustainability of transport through improving the competitiveness of the railway and waterborne modes that exhibit better environmental characteristics than road haulage.

The thesis has three objectives, all related to green corridors. The first one aims to develop a methodology for the quantitative monitoring of the performance of a green corridor in terms of pre-specified Key Performance Indicators (KPIs). The thesis builds on previous own work under the EU financed SuperGreen project and applies the new methodology on the GreCOR corridor extending from Oslo to Rotterdam. The scope of the two other objectives relates to environmental indicators viewed in the context of maritime corridors. The second objective seeks to develop a simple and practical framework for classifying the carbon emission reduction measures that have been proposed for the shipping industry, while the third one examines the impacts on modal split and emissions of designating the Mediterranean Sea as a Sulphur Emission Control Area (SECA), where stricter limits on the sulphur content of marine fuels apply.

In relation to the first objective, the thesis reviews the most important EU transport policy documents, discusses the available definitions of green corridors, identifies the characteristics that distinguish a green corridor from any other efficient corridor, and uses these characteristics as criteria to investigate the relation between the so-called ‘core network corridors’ of the trans-European transport network and the green corridor concept.

Once the rationale for a performance monitoring scheme has been established, the thesis critically reviews the SuperGreen methodology which consists of: (i) decomposing the corridor into transport chains, (ii) selecting a sample of typical chains, (iii) assessing these chains through a set of KPIs, and (iv) aggregating the chain-level KPIs to corridor-level ones using proper weights. Unlike SuperGreen that suggests a study-based approach for constructing the corridor sample, the thesis proposes founding the selection of typical chains on the outcome of specialised transport models. The periodic collection of stakeholder data on the selected ‘basket’ of transport services would then enable monitoring progress towards meeting the objectives that corridor management has set.
Greenhouse gas emissions and energy balance of biodiesel production from microalgae cultivated in photobioreactors in Denmark: a life-cycle modeling

The current use of fossil fuels is problematic for both environmental and economic reasons and biofuels are regarded as a potential solution to current energy issues. This study analyzes the energy balances and greenhouse gas emissions of 24 different technology scenarios for the production of algal biodiesel from Nannochloropsis cultivated at industrial scale in photobioreactors in Denmark. Both consolidated and pioneering technologies are analyzed focusing on strengths and weaknesses which influence the performance. Based on literature data, energy balance and greenhouse gas emissions are determined in a comparative ‘well-to-tank’ Life Cycle Assessment against fossil diesel. Use of by-products from biodiesel production such as glycerol obtained from transesterification and anaerobic digestion of residual biomass are included. Different technologies and methods are considered in cultivation stage (freshwater vs. wastewater; synthetic CO2 vs. waste CO2), harvesting stage (flocculation vs. centrifugation) and oil extraction stage (hexane extraction vs. supercritical CO2 extraction). The choices affecting environmental performance of the scenarios are evaluated. Results show that algal biodiesel produced through current conventional technologies has higher energy demand and greenhouse gas emissions than fossil diesel. However, greenhouse gas emissions of algal biodiesel can be significantly reduced through the use of ‘waste’ flows (nutrients and CO2) but there are still technical difficulties with both microalgae cultivation in wastewater as well as transportation and injection of waste CO2. In any way, a positive energy balance is still far from being achieved. Considerable improvements must be made to develop an environmentally beneficial microalgae biodiesel production on an industrial scale. In particular, different aspects of cultivation need to be enhanced, such as the use of wastewater and CO2-rich flue gas from industrial power plants. (C) 2015 Elsevier Ltd. All rights reserved.

Green Maritime Logistics: The Quest for Win-win Solutions

By green maritime logistics we mean achieving an acceptable environmental performance of the maritime transport logistical supply chain while at the same time respecting traditional economic criteria. In this paper the environmental focus is on maritime emissions. Achieving such goal may involve several trade-offs, and win-win solutions are typically sought. However, finding these solutions may be more difficult than may appear at first glance. The purpose of this paper is to provide a concise overview of the challenges of green maritime logistics and present some examples, both for greenhouse gas (GHG) and non-GHG emissions.

Green maritime transportation: Market based measures
The purpose of this chapter is to introduce the concept of Market Based Measures (MBMs) to reduce Green House Gas (GHG) emissions from ships, and review several distinct MBM proposals that have been under consideration by the International Maritime Organization (IMO). The chapter discusses the mechanisms used by MBMs, and explores how the concept of the Marginal Abatement Cost (MAC) can be linked to MBMs. It also attempts to discuss the pros and cons of the submitted proposals.

Green transportation logistics: the quest for win-win solutions
This book examines the state of the art in green transportation logistics from the perspective of balancing environmental performance in the transportation supply chain while also satisfying traditional economic performance criteria. Part of the book is drawn from the recently completed European Union project Super Green, a three-year project intended to promote the development of European freight corridors in an environmentally friendly manner. Additional chapters cover both the methodological base and the application context of green transportation logistics. Individual chapters look at the policy context; the basics of transportation emissions; Green Corridors basics; the concept of TEN-T (Trans-European Network); Benchmarking of green corridors; the potential role of ICT (Information and Communication Technologies); Green vehicle routing; Reducing maritime CO2 emissions via market based measures and speed and route optimization; Sulphur emissions; Lifecycle emissions; Green rail transportation; Green air transportation; Green inland navigation and possible areas for further research. Throughout, the book pursues the goal of "win-win" solutions and analyzes the phenomenon of "push-down, pop-up", where in a change in one aspect of a problem can cause another troubling aspect to arise. For
example, speed reduction in maritime transportation can reduce emissions and fuel costs, but could require additional ships and could raise in-transit inventory costs. Or, regulations to reduce sulphur emissions may ultimately increase CO2 elsewhere in the supply chain. The book takes stock at the various tradeoffs that are at stake in the goal of greening the supply chain and looks at where balances can be struck.

Guide til Shared Space i kommuner
Shared spaces er et emne indenfor space management og porteføljestyring som beskæftiger sig med det at dele bygninger og arealer mellem flere forskellige brugere. Shared space er her defineret som: Flere forskellige enkeltpersoner / grupper / organisationer / virksomheder, organisatorisk uafhængige af hinanden, der gør brug af den samme plads, enten samtidig eller serielt.

Hackeando los ciber-riesgos en la cadena de suministro: Para entender los controles correctos, hay que mirar el sistema
Si se consideran tanto la creciente complejidad de las redes de abastecimiento, como la consecuente exposición de estas redes a interrupciones inesperadas ocasionadas por ciber-ataques, se requiere una forma más amplia para entender los ciber-riesgos en las cadenas de suministro. En este artículo se describen algunas de las razones por las que los métodos de evaluación de riesgos actuales son insuficientes, se proporciona una analogía para entender los efectos dinámicos en una empresa, se describe en términos generales lo que significa entender los ciber-riesgos desde el punto de vista de teoría de control, y se enuncia una nueva forma de entender la resiliencia en la cadena de suministro. Nuestro trabajo propone un cambio foco desde la confiabilidad de los componentes individuales en la cadena de suministro, hacia el control y un entendimiento más profundo del sistema.

Harmonizing exposure metrics and methods for sustainability assessments of food contact materials

We aim to develop harmonized and operational methods for quantifying exposure to chemicals in food packaging specifically for sustainability assessments. Thousands of chemicals are approved for food packaging and numerous contaminates occur, e.g. through recycling. Chemical migration into food, as a function of the chemical, food, and package properties and storage conditions, is responsible for human exposure to many chemicals of concern. In addition to complying with regulatory standards, stakeholders concerned with environmental sustainability draw on strategies such as Life Cycle Assessment (LCA) and Cradle to Cradle to support packaging design. Each assessment has distinct context and goals, but can help manage exposure to toxic chemicals and other environmental impacts. Metrics and methods to quantify and characterize exposure to potentially toxic chemicals specifically in food packaging are, however, notably lacking from such assessments. Furthermore, previous case studies demonstrated that sustainable packaging design focuses, such as decreasing greenhouse gas emissions or resource consumption, can increase exposure to toxic chemicals through packaging. Thereby, developing harmonized methods for quantifying exposure to chemicals in food packaging is critical to ensure ‘sustainable packages’ do not increase exposure to toxic chemicals. Therefore we developed modelling methods suitable for first-tier risk screening and environmental assessments. The modelling framework was based on the new product intake fraction (PiF) exposure metric, with units of chemical mass taken in by exposed persons versus chemical mass within a product. To model this metric, we used analytical approximations for regulatory models. We investigated model results for various chemical -package-food combinations to facilitate operation in assessments and identify combinations of priority. Modelling results predicted with accuracy previous findings, that exposure is dependent on diffusive and partitioning behaviors according to each chemical-package-food combination. Harmonizing exposure modeling with environmental assessments, like LCA, finally facilitates including exposure to chemicals as a sustainable packaging design issue. Results were demonstrated in context of the pilot-scale Product Environmental Footprint regulatory method in the European Union. Increasing recycled content, decreasing greenhouse gas emissions by selecting plastics over glass, and adding chemicals with a design function were identified as risk management issues. We conclude developing an exposure framework, suitable for sustainability assessments commonly used for food packaging, is feasible to help guide packaging design to consider both the environment and human exposure. Future work is required for refinement and operationality. This is the first study addressing the need for quantitative, harmonized exposure metrics and methods for food packaging within sustainability assessment frameworks.
Harnessing Big-Data for Estimating the Energy Consumption and Driving Range of Electric Vehicles

This study analyses the driving range and investigates the factors affecting the energy consumption rate of fully-battery electric vehicles under real-world driving patterns accounting for weather condition, drivers' characteristics, and road characteristics. Four data sources are used: (i) up to six months driving pattern data collected from 741 drivers, (ii) drivers' characteristics; (iii) road characteristics; (iv) weather data. We found that the real-world driving range of BEVs is highly sensitive to driving pattern and weather variables. The most important determinants of energy efficiency found to be driving patterns (acceleration and speed, both non-linearly) followed by seasonal variation (a winter dummy), temperature (non-linearly) and precipitation. Mean ECR is higher by about 34% and the driving range is lower by about 25% in winter than in summer. A fixed-effects econometrics model used in this paper predicts that the energy saving speed of driving is between 45 and 56 km/h. In addition to the contribution to the literature about energy efficiency of electric vehicles, the findings from this study enlightens consumers to choose appropriate cars that suit their travel demand under the driving environment they live in, to know about energy saving patterns of drive, and to reduce driving range anxiety problem.

Health effects from indoor and outdoor exposure to fine particulate matter in life cycle impact assessment

Fine particulate matter (PM2.5) pollution has been estimated to contribute more than 7% to the total global human disease burden from 1990 to 2013 (http://healthdata.org/gbd). Ambient (outdoor) and household indoor PM2.5 exposures are reported to account for 41% and 58% of this impact, respectively, emphasizing the need to include both, outdoor and indoor exposure into overall estimates of health burdens in life cycle impact assessment. However, lacking clear guidance on how to consistently include health effects from exposure to PM2.5 in life cycle perspective, practitioners fail to report related life cycle impacts. To address this gap, a global initiative has worked on building a coupled indoor-outdoor intake fraction framework combining exposure to PM2.5 emitted indoors and outdoors with exposure to PM2.5 formed indoors and outdoors from chemical reactions. An exposure-response model derived from ambient PM2.5 concentrations is consistently combined with exposures from indoor and outdoor sources. All factors are systematically built into a model parameterized for different archetypal outdoor and indoor settings, such as specific residential and occupational settings and different urban area sizes. Model and parameters are tested in a case study on the production and processing of rice in three distinct scenarios covering urban China, rural India and U.S.-Europe. Recommendations are to use this coupled, generic framework whenever emission locations are unknown and to apply spatial models whenever emission locations are known. Our study constitutes a first step towards providing guidance on how to include health effects from PM2.5 indoor air exposures in product-oriented impact assessments.
Health effects from indoor and outdoor exposure to fine particulate matter in life cycle impact assessment

Exposure to fine particulate matter (PM2.5) pollution is a major contributor to human disease burden as continuously shown in the Global Burden of Disease study series. Exposures to PM2.5 concentration outdoors and indoors contribute almost equally to this burden. Despite the importance, health impacts from exposure to PM2.5 are often excluded from life cycle impact assessment (LCIA) characterization profiles. This is in large part because of the lack of well-vetted harmonized guidance about how to consistently assess the exposures and impacts of indoor and outdoor emissions of PM2.5 and its precursors. We present a framework for calculating characterization factors for indoor and outdoor emissions of primary PM2.5 and secondary PM2.5 precursors, and a roadmap for further refining this modelling framework for operational use in LCIA. The framework was developed over the last three years by a task force convened under SETAC/UNEP auspices and culminating in a recent international expert workshop, to provide guidance and methods for estimating the health impacts associated with PM2.5 exposure and to recommend PM2.5 characterization factors for application in life cycle assessment. The framework involves three stages – analyzing PM2.5 fate and exposure (including indoor and outdoor urban/rural environments), modeling exposure-response, and the integration of exposure-response and PM2.5 exposure reflecting population and location characteristics. Our exposure model is organized as a mass balance matrix that tracks the global fate of primary PM2.5 and secondary PM2.5 precursor emissions (both indoors and outdoors) as an embedded system of compartments including urban environments, rural environments, and indoor environments within urban and rural areas. After presenting the model structure, we will review initial results and will present geographic variability, discuss key uncertainties, and evaluate our model using results from other models and concentration measurements.
Heat supply planning for the ecological housing community Munksøgård

Munksøgård is a housing community near the city of Roskilde, Denmark. In 2014, Munksøgård's residents have agreed to change the existing heat supply system. The choice of future heat supply was narrowed to heat pumps, new biomass boiler and connection to nearby district heating network. The present paper compares results from techno-economic energy system analysis, simple private-economic analysis and assessment of externalities related to the heat supply and discusses the differences in conclusions - is the economic optimal solution different from a system or private-economic point of view? The techno-economic energy system analysis is done using TIMES-DTU model, which optimizes over all sectors in Denmark and all periods until 2050. The result from this model gives the least expensive solution from the overall system point of view. A spreadsheet model has been developed to do the private-economic analysis and the evaluation of external effects related to the different solutions.
HESI pilot project: Testing a qualitative approach for incorporating exposure into alternatives assessment

Most alternatives assessments (AA) published to date are largely hazard-based rankings, and as such may not serve to determine a practical and functional replacement. With an assessment goal of identifying an alternative chemical that is more sustainable, other attributes beyond hazard are also important, including exposure, risk, life-cycle thinking, performance, cost, and social responsibility. Building on the 2014 recommendations by the US National Academy of Sciences to improve AA decisions by including comparative exposure assessment, the HESI Sustainable Chemical Alternatives Technical Committee, which consists of scientists from academia, industry, government, and NGOs, has developed a qualitative comparative exposure approach. Conducting such a comparison can screen for alternatives that are expected to have a higher exposure potential, which could trigger a higher-tiered, more-quantitative exposure assessment on the alternatives being considered.

This talk will demonstrate an approach for including chemical and product exposure information in a qualitative AA comparison. Starting from existing hazard AAs, a series of four exposure examples were examined to test the concept, to understand the effort required, and to determine the value of exposure data in AA decision-making. The group has developed ingredient and product parameter categorization to support comparisons between chemicals and methodology to address data quality. The ingredient parameters include a range of physicochemical properties that can impact exposure, while the product parameters include aspects such as exposure pathway, use pattern, frequency/duration of use, concentration in product and use volume, accessibility, and disposal. Key learnings, challenges, and opportunities for further work will also be presented.
High-throughput exposure modeling to support prioritization of chemicals in personal care products

We demonstrate the application of a high-throughput modeling framework to estimate exposure to chemicals used in personal care products (PCPs). As a basis for estimating exposure, we use the product intake fraction (PiF), defined as the mass of chemical taken by an individual or population per mass of a given chemical used in a product. We calculated use- and disposal-stage PiFs for 518 chemicals for five PCP archetypes. Across all product archetypes the use- and disposal-stage PiFs ranged from 10−5 to 1 and 0 to 10−3, respectively. There is a distinction between the use-stage PiF for leave-on and wash-off products which had median PiFs of 0.5 and 0.02 across the 518 chemicals, respectively. The PiF is a function of product characteristics and physico-chemical properties and is maximized when skin permeability is high and volatility is low such that there is no competition between skin and air losses from the applied product. PCP chemical contents (i.e. concentrations) were available for 325 chemicals and were combined with PCP usage characteristics and PiF yielding intakes summed across a demonstrative set of products ranging from 10−8–30 mg/kg/d, with a median of 0.1 mg/kg/d. The highest intakes were associated with body lotion. Bioactive doses derived from high-throughput in vitro toxicity data were combined with the estimated PiFs to demonstrate an approach to estimate bioactive equivalent chemical content and to screen chemicals for risk.

How do dynamic capabilities transform external technologies into firms' renewed technological resources? – A mediation model

How externally acquired resources may become valuable, rare, hard-to-imitate, and non-substitute resource bundles through the development of dynamic capabilities? This study proposes and tests a mediation model of how firms' internal technological diversification and R&D, as two distinctive microfoundations of dynamic technological capabilities, mediate the relationship between external technology breadth and firms' technological innovation performance, based on the resource-based view and dynamic capability view. Using a sample of listed Chinese licensee firms, we find that firms must broadly explore external technologies to ignite the dynamism in internal technological diversity and in-house R&D, which play their crucial roles differently to transform and reconfigure firms' technological resources.

How flexible is flexible? Accounting for the effect of rescheduling possibilities in choice of departure time for work trips

In departure time studies it is crucial to ascertain whether or not individuals are flexible in their choices. Previous studies have found that individuals with flexible work times have a lower value of time for late arrivals. Flexibility is usually measured in terms of flexible work start time or in terms of constraints in arrival time at work. Although used for the same purpose, these two questions can convey different types of information. Moreover, constraints in departure time are often related not only to the main work activity, but to all daily activities. The objective of this paper is to investigate the effect of constraints in work and in other daily trips/activities on the willingness to shift departure time and the willingness to pay for reducing travel time and travel delay. We set up a survey to collect detailed data on the full 24-hour out-of-home activities and on the constraints for each of these activities. We then built a stated preference experiment to infer preferences on departure time choice, and estimated a mixed logit model, based on the scheduling model, to account for the effects of daily activity schedules and their constraints. Our results show that measuring flexibility in terms of work start time or constraints at work does not provide exactly the same information. Since one-third of the workers with flexible working hours in the survey indicated that they have restrictions on late work-arrival times, their willingness to pay will be overestimated (almost doubled) if flexibility information is asked only in terms of fixed/flexible working hours. This clearly leads to different conclusion in terms of demand sensitivity to reschedule to a later departure time. We also found that having other activities and constraints during the day increases the individuals' willingness to pay to avoid being late at work, where the presence of constraints on daily activities other than work is particularly relevant for individuals with no constraints at work. The important impact of these findings is that if we neglect the presence of constraints, as is common practise in transport models, it will generally lead to biased value-of-time estimates. Results clearly show that the shift in the departure time, especially towards a late departure time, is strongly overestimated (the predicted shift is more than double) when the effect of non-work activities and their constraints is not accounted for.
How much biochar does gasification energy need to be carbon neutral?

Indirect land use changes (iLUC) from bioenergy emerge whenever an energy crop is planted in arable land. Due to their overarching magnitude from a life-cycle perspective, they have been repeatedly recommended to be included in bioenergy’s greenhouse gas (GHG) accountings, despite their challenging quantification and inherent uncertainties. Marginal or abandoned lands have been often quoted as the solution to avoid these undesired effects from bioenergy. However, land abandonment and marginalization is to a large extent a socio-economic process, and thus heavily depends on specific, constantly changing socio-political context and economic circumstances in place. We suggest a carbon negative bioenergy system that compensates for potential iLUC emissions and losses in soil organic carbon (SOC). A consequential life cycle assessment on willow bioenergy has been performed, distinguishing marginal and arable land scenarios. Specific soil types and their estimated SOC changes have been considered [9], as well as iLUC emissions for the arable case. Taking the study case of a willow plantation combined with a medium-scale gasification plant in Denmark, we illustrate the biochar needed from the process in order to remain carbon neutral. The time scopes assessed are 20 and 100 years and it is assumed a fossil fuel (FF) free Denmark beyond 2050 as targeted by government (no FF displacement occurs after 2050). Results show that willow on marginal land remains carbon negative (4% biochar fraction) for the short term, while as much as 31.8% of biochar (or 0.95 Mg C ha⁻¹ yr⁻¹) would be necessary in 100 years to be carbon neutral (taking natural vegetation as reference baseline). As for arable land willow, a biochar fraction of 34.1% (or 2.32 Mg C ha⁻¹ yr⁻¹) would be necessary in the short term to compensate for iLUC emissions, while a 4% would suffice to make it carbon negative in the long term, as iLUC “dilutes” over 100 years. To achieve such high biochar fractions (>10%), lower process temperatures are needed, which affect negatively the long-term stability of biochar. This can put at risk the claimed GWP reduction benefits. This study did not consider impacts on other environmental aspects as ecosystem services and biodiversity, which are deemed to be rather important and significant for iLUC.

How (not) to pay - Field experimental evidence on the design of REDD plus payments

Payments for Ecosystem Services (PES) can use many design features. We investigate the impact of payment conditionality types, i.e. different specifications when to pay and when not to pay, for PES on deforestation and agricultural production in a lab-in-the-field experiment. Our experiment also tests variations in contract period and payment volatility. We designed a highly visual simulation game to characterize the decision situation of a cattle rancher in Brazil. The player can expand extensive pasture by deforestation or intensify existing pasture. The model includes both a land and a capital constraint. We applied the game in an economic, framed lab-in-the field experiment in Tocantins, Brazil. Payments conditional on forest carbon stock lead to slow, but steady deforestation, while payments conditional on forest carbon stock-change suppressed deforestation more strongly. But payments conditional on stock increase cattle production while payments conditional on stock-change have no effect on production. Thus, depending on the level of leakage, either type of conditionality can be more cost-effective in reducing global carbon emissions. Contracts with limited periods lead to strong deforestation after the end of the payment period. Payment volatility had no significant effect. (C) 2016 Elsevier B.V. All rights reserved.
How Positive Practices Can Accelerate Transformation To a Lean Improvement Culture

With increasing pressure on creating more value with fewer resources, many organizations pursue continuous improvement culture and practices in daily operations. In operations management, Lean and the Toyota Way have been continuous improvement role models for describing tools and culture. However, the cultural transformation has been reported difficult to achieve. This study investigates how practices in daily operations can be used to purposely support the cultural transformation. During an explorative case study, 9 practices were identified and analyzed. The study showed that positive practices based on appreciative inquiry and positive psychology were particularly effective in accelerating cultural transformation.

How to consistently make your product, technology or system more environmentally-sustainable?

Human activities are currently unsustainable, causing many damages to ecosystems, human health and natural resources. In this setting, the development of new products and technologies has been increasingly required to relate to sustainability and ensure that such development goes hand-in-hand with low environmental impacts, low-carbon emissions, low environmental footprints or more sustainability as a whole. To enable a scientifically-sound and consistent documentation of such sustainable development, quantitative assessments of all environmental impacts are needed. Life cycle assessment (LCA) is recognized as the most holistic tool to address that need. LCA has two main strengths: (1) the ability to quantify all relevant environmental impacts – not just climate change, but also metal depletion, water use, toxicity exerted by pollutants on ecosystems and human health, etc.; and (2) making the assessment of the product/technology in a life cycle perspective, from the extraction of raw materials through production and use/operation of the product up to its final disposal. Fully embracing these 2 features enables to minimize the risk of burden-shifting, e.g. if impacts on climate change are being reduced while increasing other relevant environmental impacts or if impacts are shifted from the use stage of a product to the manufacturing stage as a result of a change in the product composition. Here, we provide a glimpse at how LCA can help for eco-design purposes, moving towards the use of low-impact materials, identifying environmental hotspots parts of the life cycle with largest environmental impacts), making prospective simulations through scenario analyses, comparing and selecting most environmentally-friendly product/technology alternatives, reporting on the environmental performances of the system. We rely on state-of-the-art science in the food sector, the aquaculture sector and the energy sector to showcase and illustrate the potential of LCA to undertake the environmental sustainability challenge and support product/technology/system development.

Hvad ved bilister egentlig om sikkerhedsteknologi i biler?
Potentialet for forbedret trafiksikkerhed gennem sikkerhedsteknologi er stort. En ny amerikansk undersøgelse viser dog, at bilisternes kendskab til og forståelse af hvordan sikkerhedssystemerne virker og skal benyttes er begrænset, selv for sikkerhedsudstyr der i dag har stor udbredelse som fx ABS-bremser. Der er således behov for en informationsindsats ikke mindst i lyset af forventningen om stigende udbredelse af sikkerhedsteknologi i bilparken fremover.

Hvem skal overleve?
Konflikter i trafikken er uundgåelige, også selv om de måske bliver minimeret i forbindelse med selvkørende biler. I forbindelse med udviklingen af selvkørende biler, er det derfor nødvendigt, at der udarbejdes nogle principper for, hvordan selvkørende biler skal håndtere forskellige typer af konflikter, herunder de etiske og moralske dilemmaer der kan opstå.

Identification of Parameters Affecting the Variability of Energy Use in Residential Buildings

Energy use of buildings varies significantly. When aggregating the demand profiles of a group of buildings, the variations of energy demand are critical to determine the aggregated load profile. Especially when dimensioning district energy systems, it is important to know the variability of energy demand that can guarantee the efficient operation of the system. For this reason, it is useful to distinguish the parameters that affect building energy performance the most and to estimate the magnitude of these variations on each parameter. The aim of the present study is to identify the parameters that lead to the largest variations in energy performance of residential buildings in Denmark. A set of sensitivity analysis has been carried out using an extensive search algorithm. These sensitivity analyses were then applied for modelling a reference building representing Danish single-family houses of the 1940’s. The study was able to determine the key variables that affect energy use in old Danish single-family houses using sensitivity analysis and proposes a methodology for parameter optimization. This analysis pointed out that the insulation in external walls and roof lead to the largest variations in space heating demand. Also, the infiltration rate and occupancy behavior play important role on space heating consumption. It was concluded that these findings highly depend on the specific case study and the characteristics of the buildings that are examined. If outdoor climate and location differ from the current case, a different set of parameters should be investigated upon its effect on building energy use.
Identification of risks stemming from new communication technologies

Advanced distributed communication technologies play an important role today in the control and maintenance of safety-critical systems. However, the excessively optimistic reliance on the new technology without recognizing the threats against its successful functioning, being able to maintain barriers or/and eliminate or reduce the risks may result in impairments compromising the opportunities. At the current state of knowledge it is even unclear whether we can develop trustful causal paths between hazards of different natures and their consequences. Hazard identification and risk analysis have proved to be effective tools in developing more reliable and robust systems. As technology is developing fast though, a new need for an effective hazard identification methodology has emerged. To enhance the predictive performance of hazard identification in advanced distributed communication systems, we have envisioned and currently developing a multilevel-multidimensional HAZOP methodology. The methodology introduces a new creative thinking stimulation model to substitute the conventional guideword-based approaches that is based on a multiple level and dimension exploration of the system under consideration. This paper describes the work carried out to extend the standard HAZOP approaches to suit the analysis of new communication technologies based on a simple corrective maintenance scenario taking place at a Nuclear Power Plant.

Impact of Personnel Capabilities on Organizational Innovation Capability
One of the most dynamic capabilities that lead to the strongest competitive advantage in the organizations is the innovation capability. Analysing the development of a firm’s innovation capability is an important research project, and can help organizations to achieve competitive advantage in this rapidly changing world. This research focuses on definition of the personnel aspect of innovation capability, and proposes a conceptual model based on the scientific articles of academic literature on organisations innovation capability. This paper includes an expert based validation in three rounds of the Delphi method. And for the purpose of a better appreciation of the relationship dominating the factors of the model, it has distributed the questionnaire to Iranian companies in the Food industry. This research proposed a direct relationship between Innovation Capability and the Personnel Capability. Also, it offers the most important components and indices which directly influence and are related to the Innovation Capability.

Impact of the utilization of a product configuration system on product’s life cycle complexity
The purpose of this paper is to identify areas throughout a product's lifecycle processes where complexity can be reduced by implementing a product configuration system (PCS). As discussed in the literature, several benefits are realized by using a PCS in terms of product and process standardization. This also leads to control and reduce of complexity both in products and processes. To this end, this research attempts to quantify and assess these benefits and is supported by empirical evidence. A case study of an engineering company is used and the results indicate significant improvements for the company in several life cycle processes.

Impacts of urban development and climate change in exposing cities to pluvial flooding

Urban areas are characterized by very high concentrations of people and economic activities and are thus particularly vulnerable to flooding during extreme precipitation. Urban development and climate change are among the key drivers of changes in the exposure of cities to the occurrence and impacts of pluvial flooding. Cities are often dominated by large areas of impervious surfaces, that is, man-made sealed surfaces which water cannot penetrate, and increases in these – for example, as a consequence of urban development – can cause elevated run-off volumes and flood levels during precipitation. Climate change is expected to affect the intensity and frequency of extreme precipitation, with increases projected for many regions, including most parts of Europe.

Implementation of Auctions for Renewable Energy Support in Croatia: A case study

This report deals with the planned implementation of auctions for Renewable Energy support in Poland from 2016 onwards. The report focuses on the implementation process and provides the necessary background information. Furthermore the planned auction design is described and discussed both from a policy maker’s and an investor’s point of view. Finally, main strengths and weaknesses are identified and the scheme is discussed according to several success criteria. The proposed design is related to the findings from AURES work packages 2, 3 and 4, which included the identification of success criteria, of appropriate auction formats and suitable design elements for RES auctions, as well as the analysis of past auction implementations.
This report deals with the potential implementation of opened auctions for Renewable Energy support in the Netherlands from 2017 on. The report focuses on the implementation process and provides the necessary background information. Furthermore, the planned auction design is described and discussed both from a policy maker’s and an investor’s point of view. Finally, main strengths and weaknesses are identified and the scheme is discussed according to several success criteria. The proposed design is related to the findings from AURES work packages 2, 3 and 4, which included the identification of success criteria, of appropriate auction formats and suitable design elements for RES auctions, as well as the analysis of past auction implementations.

Improved Performance and Quality of Configurators by Receiving Real-Time Information from Suppliers
Companies providing customized products are increasingly applying configurators in order to support the sales and design activities. Yet, especially for engineer-to-order (ETO) companies such activities are often divided across different organizations, where throughout the configuration process product specification has to be retrieved across the supply chains. Therefore, it is required that relevant information from suppliers is included in the configuration process, either as sub-models or by integrating configurators across the supply chains. This study investigates the challenges associated with including suppliers’ product specifications as sub-models and how these can be addressed by integrating configurators across supply chains to receive real-time information from suppliers. Based on established literature on the
illustrated technical integration of configurators across the supply chains, this paper contributes with empirical evidence on the overall impact of its implementation. The results presented are based on a case study in an ETO company where it is supported that the complexity of the configuration models can be significantly reduced as well as the time devoted for the modelling and maintaining the systems. Furthermore, with the ability of receiving accurate and up-to-date information from suppliers, the quality of the specifications can be improved, which leads to reduced cost of the overall design.

**Improving Creativity Training: A Study of Designer Skills**

Creativity is widely accepted to be a crucial element in design, and design has traditionally been a popular domain for creativity studies. Moreover, creativity has repeatedly been shown to be an important element for design and innovation e.g. [Christiaans 1992], [Amabile et al. 1996], [Dorst and Cross2001]. Establishing that creativity is important for design and innovation implies that identifying ways of improving creativity is a relevant research area within design studies. Creativity is a basic human skill and multiple studies have been published showing that creativity is a skill that can be trained (see e.g. [Scott et al. 2004] for a review of these). Despite establishing that creativity training works, it is though not yet clear how individual creativity skills can influence the creative process, although many studies have been published on different types of creativity training formats e.g. [Scott et al. 2004], [Robbins and Kegley 2010]. The aim of this study was therefore to investigate how individual creativity skills influence the creative process of design teams working within the fuzzy front end (as defined in [Koenet al. 2002]) of innovation; an important first step in identifying which individual creativity skills should be trained in designers. An exploratory study was designed, using participatory observation of two design teams in a six-month case study in two major organizations, with individual skills being the unit of analysis. The focus of the study was to observe the process the teams operated within and its progress when individuals applied their creativity skills to advance its progress, while the intent was not to assess the creative product or output as such. Design is a collaborative effort and creativity has to be understood both on an individual and on a team level. In creativity research, the ‘standard definition of creativity’ [Runco and Jaeger 2012] defines creativity as the production of something new and appropriate for a specific context, thus bringing value to its prospective users [Stein 1953]. Onarheim and Friis-Olivarius [2013] suggest that ‘new’ is related to divergent thinking, the process of coming up with multiple solutions, while ‘appropriate’ coincides with convergent thinking, the process of taking those multiple ideas and converging them into an appropriate solution. Divergent thinking is here considered somewhat a ‘solo sport’, as producing ideas is often considered as a cognitive individual task [Onarheim 2011], whereas convergent thinking could be thought of as a ‘team sport’ – teams are good at selecting ideas and are likelier to successfully complete the task [Singh and Fleming 2010]. Thus, creativity training for designers should not only be directed at the individual level by enhancing individual creativity skills, but also improvement at the team level, rendering it important to first improve the understanding of both these levels of creativity in the design process. There are multiple ways to train creativity, although currently most creativity training is directed at enhancing individual creativity skills, usually measured through the ability to generate ideas, i.e. divergent thinking [Guilford 1959]. However, as individually focused as creativity training might seem, DESIGN INNOVATION 1175Scott et al. [2004] concluded that the most optimal way of training creativity is through a combination of (1) educating individuals about creativity, thereby building a solid theoretical understanding, and (2) providing them with a real world case where they are trained in the use of creative tools and processes[Scott et al. 2004]. The latter point has great implications for creativity training for designers, as in the real world designers rarely work in a void but in teams and thus the team interactions should be taken into account in creativity training for designers. Here we understand the team as an entity, independent from, yet influenced by the organization, however largely dependent on individuals; the individuals that make up the team (following [Woodman et al. 1993]). With that in mind the current study was designed to investigate individuals and how they operate in teams, thus focusing both on the individual level as well as the team level and their respective importance and contribution to the creative process of design teams. In the following chapters a theoretical overview is first provided about the individual- and team level in regards to creativity literature. Next, a description of the case study and the methods deployed in the context of the case study is given. Chapter four contains the findings of the study and chapter five provides a discussion and subsequent conclusions drawn from the
Improving plant bioaccumulation science through consistent reporting of experimental data

Experimental data and models for plant bioaccumulation of organic contaminants play a crucial role for assessing the potential human and ecological risks associated with chemical use. Plants are receptor organisms and direct or indirect vectors for chemical exposures to all other organisms. As new experimental data are generated they are used to improve our understanding of plant-chemical interactions that in turn allows for the development of better scientific knowledge and conceptual and predictive models. The interrelationship between experimental data and model development is an ongoing, never-ending process needed to advance our ability to provide reliable quality information that can be used in various contexts including regulatory risk assessment. However, relatively few standard experimental protocols for generating plant bioaccumulation data are currently available and because of inconsistent data collection and reporting requirements, the information generated is often less useful than it could be for direct applications in chemical assessments and for model development and refinement. We review existing testing guidelines, common data reporting practices, and provide recommendations for revising testing guidelines and reporting requirements to improve bioaccumulation knowledge and models. This analysis provides a list of experimental parameters that will help to develop high quality datasets and support modeling tools for assessing bioaccumulation of organic chemicals in plants and ultimately addressing uncertainty in ecological and human health risk assessments.
India’s GHG Emission Reduction and Sustainable Development

India has made voluntary commitment for reducing the emission intensity of GDP in the year 2020 by 20–25 % below that in the year 2005. The Indian approach is based on delineating and implementing cost-effective mitigation actions which can contribute to national sustainable development goals while remaining aligned to the UNFCCC’s expressed objective of keeping the average global surface temperature increase to below 2 C over the preindustrial average. This chapter assesses three emission scenarios for India, spanning the period 2010–2050. The analysis is carried out using a bottom-up energy system model ANSWER-MARKAL, which is embedded within a soft-linked integrated model system (SLIMS). The central themes of the three scenario storylines and assumptions are as follows: first, a business-as-usual (BAU) scenario that assumes the socioeconomic development to happen along the conventional path that includes implementation of current and announced policies and their continuation dynamically into the future; second, a conventional low carbon scenario (CLCS) which assumes imposition, over the BAU scenario, of CO2 emission price trajectory that is equivalent to achieving the global 2 C target; and third, a sustainable scenario that assumes a number of sustainability-oriented policies and measures which are aimed to deliver national sustainable development goals and which in turn also deliver climate mitigation, resilience, and adaptation as co-benefits. The sustainable low carbon scenario (SLCS) also delivers same cumulative emissions from India, over the period 2010–2050, as the CLCS scenario using carbon price as well as a mix of sustainability-oriented policies and measures. The scenario analysis provides important information and insights for crafting future policies and actions that constitute an optimal roadmap of actions in India which can maximize net total benefits of carbon emissions mitigation and national sustainable development. A key contribution of the paper is the estimation of the net social value of carbon in India which is an important input for provisioning carbon finance for projects and programs as an integral part of financing NAMAs. The analysis in the paper will be useful for policymakers seeking to identify the CO2 mitigation roadmap which can constitute an optimal mix of INDCs for India.
Indicators and beyond: Assessing the sustainability of transport projects

Credibly demonstrating actual progress towards a genuinely sustainable transport situation remains a challenge. A key problem is that the incorporation of sustainability in transport policy and planning at present is not systematic. A motivating assumption behind this thesis is that a transition toward a sustainable transport system will require strong support from decision-support processes and assessment tools that do not only adopt the language of sustainability, but fully integrate an explicit notion of sustainability in all of their conceptual, operational and procedural approaches. There is therefore a general need to improve processes, methods and tools applied in transport infrastructure decision making so as to make them more resonant to the needs of both current and future generations corresponding to the fundamental definition of sustainable development.

The core focus of the thesis is on how to ensure project impacts in terms of sustainability are identified and become inputs to decision making.

The benefits of increased mobility based on speed and capacity are significant and visible, creating a wide range of reachable activities for a great number of people. Negative externalities of transport systems such as accidents, local air pollution and noise have long been monetised and accounted for in conventional transport project appraisal. But the transport sector today (in Denmark, in the EU and globally) is also an increasingly large contributor to the two core planetary boundaries of climate change and biosphere integrity. Such wider, more complex and longer terms effects that are also external to local interests and market transactions are not only increasingly observed in transport but are also far less well accounted for. The risk here is that evidence-based decision-making becomes discredited, as was already found to be the case for high-speed rail appraisal in the UK, which is the most important case analysed in this thesis.

This thesis contributes to the following three challenges: the overarching conceptualisation of sustainable development as an ethos for transport infrastructure policy, the operational specifics of impact assessment based on indicators and methods for their prioritisation, and stakeholder representations applied in assessment procedures, with a particular focus on creating a explicit ‘future generations’ viewpoint. The research takes a starting point in Sustainable Transport Indicator Frameworks (STIFs), then expands to decision-support processes and assessment tools, and finally explores issues relevant for the wider field of transport planning and decision-making.

A main underlying concern of the research is to develop new thinking and assessment methods that bridge the technorationalist/instrumental approach of conventional impact assessment tools with a wider communicative planning rationality. This is needed because of the complex, dynamic and interdependent nature of transport planning and decision-making.

Methods

This thesis draws from multiple research methods which are both qualitative and quantitative. For the conceptual work, I rely on purposive literature reviews, including extensive reviews on sustainability theory and the implication of this body of knowledge for sustainable transport, as well as a detailed review of selected literature on the topic of sustainable transport indicator frameworks. Case study work draws upon extensive desktop-based analysis of impact assessment reports and other publicly available material about real cases of large transport infrastructure appraisals. The HS2 high-speed rail (HSR) project appraisal in the UK is used as a case study in three of the articles that compose this thesis, first because of the long tradition for comprehensive and open appraisal processes in the UK, and second for the significant wider environmental, social and economic impacts of the scheme, which is an opportunity to examine sustainability in the context of transport appraisal in more detail.

The work specifically concerned with the elaboration of assessment tools and decision-support processes is based on an adaptation of multi-criteria analysis tools (MCA) and more particularly on the Multi-Actor Multi-Criteria Analysis (MAMCA) approach, which gives more prominence to the explicit integration of stakeholders in transport project appraisal. Empirical work was conducted ex-post and consists of structured interviews based on online questionnaires following standard MCA steps. Finally in order to complement the research I also conduct exploratory work consisting of face-to-face unstructured interviews and structured observation of passengers’ activities in actual high-speed rail trips in the UK.
Exposure to fine particulate matter (PM2.5) is a major contributor to the global human disease burden. The indoor environment is of particular importance when considering the health effects associated with PM2.5 exposures because people spend the majority of their time indoors and PM2.5 exposures per unit mass emitted indoors are two to three orders of magnitude larger than exposures to outdoor emissions. Variability in indoor PM2.5 intake fraction (iFin,total), which is defined as the integrated cumulative intake of PM2.5 per unit of emission, is driven by a combination of building-specific, human-specific, and pollutant-specific factors. Due to a limited availability of data characterizing these factors, however, indoor emissions and intake of PM2.5 are not commonly considered when evaluating the environmental performance of product life cycles. With the aim of addressing this barrier, a literature review was conducted and data characterizing factors influencing iFin,total were compiled. In addition to providing data for the calculation of iFin,total in various indoor environments and for a range geographic regions, this paper discusses remaining limitations to the incorporation of PM2.5-derived health impacts into life cycle assessments and makes recommendations regarding future research.

Manufacturing companies are increasingly seeking to gain the benefits from mass customization strategies as a response to increased customers' demand for customized products. To automate the process of generating products’ specifications and guide the sales process, configurators are commonly used to support companies applying mass customization strategies. This article analyzes the relationship between the initial motivations manufacturing companies have for implementing configurators and the realized benefits from the application of configurators. The results presented in this paper are based on a survey followed with interviews in 22 industrial companies. The findings show that the main motivations can be grouped into seven categories, where the successfulness of achieving the targeted benefits varies between the individual categories. Furthermore, the results highlight that substantial benefits can be achieved when applying configurators in manufacturing companies.
Infrastructure and spatial effects on the frequency of cyclist-motorist collisions in the Copenhagen Region

Promoting cycling aims at reducing congestion and pollution as well as encouraging healthy and sustainable lifestyles but generally clashes with the perception of crash risk while riding a bicycle that is still the most significant disincentive to cycling. This study sheds light on the factors affecting the probability of cyclist-motorist collisions while accounting for heterogeneity and spatial correlation. The current study analyzed the factors contributing to increase crash risk while riding a bicycle by focusing on 5,349 cyclist-motorist collisions within 269 traffic zones in the Copenhagen Region. The model controlled for traffic exposure for bicycles and motorized transport modes, evaluated the effects of infrastructure and socioeconomic characteristics of the zones, and accounted for heterogeneity and spatial correlation across the zones. A Poisson-lognormal model with second-order conditional autoregressive (CAR) priors confirmed the existence of the safety in numbers phenomenon, contradicted previous literature about bicycle facilities not being helpful in reducing crash risk, highlighted the need for Copenhagen-style bicycle paths especially in suburban areas, and emphasized how heterogeneity and spatial correlation play a significant role in explaining the probability of cyclist-motorist crash occurrence.
Infrastruktureffekter på færdselsuheld
Sikre Veje og Asfaltindustrien er gået sammen med DTU i et spændende forskningsprojekt med det formål at undersøge infrastrukturens betydning for færdselsuheld. Et forbedret datagrundlag har gjort det muligt at afdække, hvilke infrastruktureffekter der har indflydelse på alvorlighedsgraden og antallet af færdselsuheld i Danmark. Derved er der mulighed for at forbedre de nuværende vurdering- og prioriteringsmetoder som bruges, når infrastrukturelementer skal forbedres på vejnettet.

Integrated approach for characterizing and comparing exposure-based impacts with life cycle impacts

To address hazardous chemicals in consumer products, chemical alternatives assessment (CAA) is an emerging approach combining hazard and exposure assessment with technical and economic feasibility. Life cycle aspects are typically not consistently considered in CAA, but are relevant to avoid decisions that involve burden shifting or that result in only incremental improvement. Focusing in the life cycle impacts on widely accepted and applied impact categories like global warming potential or cumulative energy demand aggregating several impact categories will lead to underestimations of life cycle emissions of potentially harmful chemicals and their proposed replacements. Hence, an assessment framework is required that is able to account for near-field consumer exposure to chemicals in products during and after product use as well as population far-field exposure to chemical emissions to the environment from product-related processes along the product life cycle. We build on a flexible mass balance-based modeling system yielding cumulative multimedia transfer fractions and exposure pathway-specific Product Intake Fractions defined as chemical mass taken in by humans per unit mass of chemical in a product. When combined chemical masses in products and further with toxicity information, this approach is a resourceful way to inform CAA and minimize human exposure to toxic chemicals in consumer products through both product use and environmental emissions. We use an example of chemicals in consumer products to demonstrate how this matrix-based system offers a consistent and efficient way to compare exposure pathways for different user groups (e.g. children and adults) and the general population exposed via the environment. We further compare toxicity-related outcomes with outcomes from other life cycle impacts to compare the relevance of different impact categories for different consumer product classes. Through our examples, we will show (a) how to align assumptions used in different assessment methods in a manner that can avoid contradictory results, (b) to consistently consider and compare all relevant impacts, thereby avoiding burden shifting that could result from disregarding chemical and product life cycles, and (c) to prioritize the most relevant impacts across all life cycle stages, thereby setting the scene for a “life cycle alternatives assessment” (LCAA).
Integrated indoor and outdoor exposure assessment framework for fine particulate matter pollution

The 2010 Global Burden of Disease report demonstrates that fine particulate matter (PM2.5) pollution is the major environmental contributor to mortality. Exposures outdoors (ambient) and indoors (household) contribute almost equally to this burden. Unfortunately, the health impacts from exposure to PM2.5 are often excluded from life cycle impact assessment (LCIA) used for characterizing environmental performance of products and services. This is in large part because of the lack of well-vetted harmonized guidance about how to consistently assess the exposures and impacts of indoor and outdoor emissions of PM2.5 and its precursors. We present a modeling framework for calculating exposure factors for indoor and outdoor emissions of primary PM2.5 and secondary PM2.5 precursors, and a roadmap for further refining this modelling framework for operational use in LCIA. The framework was developed over the last three years by a task force convened under auspices of the Society of Environmental Toxicology and Chemistry (SETAC)/United Nations Environment Program (UNEP) Life-Cycle Initiative to provide guidance and methods for estimating the health impacts associated with PM2.5 exposure and to recommend PM2.5 characterization factors for application in life cycle assessment. The framework involves three stages—analyzing PM2.5 fate and exposure (including indoor and outdoor urban/rural environments), modeling exposure-response, and the integration of exposure-response and PM2.5 exposure reflecting population and location characteristics. We introduce the overall framework and present key components of the exposure assessment underlying the health impact characterization factors. The exposure metric at the center of this analysis is the population intake fraction (IF). Our exposure model is organized as a mass balance matrix that tracks the global fate of primary PM2.5 and secondary PM2.5 precursor emissions (both indoors and outdoors) as an embedded system of compartments including urban environments, rural environments, and indoor environments within urban and rural areas. The fate modeling system provides PM2.5 concentrations that are linked with human activity patterns and population geographical distribution patterns to determine intake fractions. After presenting the model structure, we will review initial results and will present geographic variability, discuss key uncertainties, and evaluate our model using results from other models and concentration measurements.
BACKGROUND:
The integration of ergonomics knowledge into engineering projects leads to both healthier and more efficient workplaces. There is a lack of knowledge about integrating ergonomic knowledge into the design practice in engineering consultancies.

OBJECTIVES:
This study explores how organizational resources can pose constraints for the integration of ergonomics knowledge into engineering design projects in a business-driven setting, and how ergonomists cope with these resource constraints.

PARTICIPANTS:
An exploratory case study in an engineering consultancy was conducted. A total of 27 participants were interviewed.

METHODS:
Data were collected applying semi-structured interviews, observations, and documentary studies. Interviews were transcribed, coded, and categorized into themes.

RESULTS:
From the analysis five overall themes emerged as major constituents of resource constraints: 1) maximizing project revenue, 2) payment for ergonomics services, 3) value of ergonomic services, 4) role of the client, and 5) coping strategies to overcome resource constraints.

CONCLUSION:
We hypothesize that resource constraints were shaped due to sub-optimization of costs in design projects. The economical contribution of ergonomics measures was not evaluated in the entire life cycle of a designed workplace. Coping strategies included teaming up with engineering designers in the sales process or creating an alliance with ergonomists in the client organization.

Integrating exposure into chemical alternatives assessment using a qualitative approach

Most alternatives assessments (AA) published to date are largely hazard-based rankings, and as such may not represent a fully informed consideration of the advantages and disadvantages of possible alternatives. With an assessment goal of identifying an alternative chemical that is more sustainable, other attributes beyond hazard are also important, including exposure, risk, life-cycle impacts, performance, cost, and social responsibility. Building on the 2014 recommendations by the U.S. National Academy of Sciences to improve AA decisions by including comparative exposure assessment, the HESI Sustainable Chemical Alternatives Technical Committee, which consists of scientists from academia, industry, government, and NGOs, has developed a qualitative comparative exposure approach. Conducting such a comparison can screen for alternatives that are expected to have a higher exposure potential, which could trigger a higher-tiered, more quantitative exposure assessment on the alternatives being considered. This talk will demonstrate an approach for including chemical- and product-related exposure information in a qualitative AA comparison. Starting from existing hazard AAs, a series of four chemical-product application scenarios were examined to test the concept, to understand the effort required, and to determine the value of exposure data in AA decision-making. The group has developed a classification approach for ingredient and product parameters to support comparisons between alternatives as well as methodology to address data quality. The ingredient parameters include a range of physicochemical properties that can impact routes and magnitude of exposure, while the product parameters include aspects such as exposure pathways, use pattern, frequency/duration of use, chemical concentration in product, and use volume, accessibility, and disposal. Key learnings, challenges, and opportunities for further work will also be presented. The views expressed in this presentation do not necessarily reflect the views or policies of the U.S. Environmental Protection Agency.

Integrating Life-cycle Assessment into Transport Cost-benefit Analysis

Traditional transport Cost-Benefit Analysis (CBA) commonly ignores the indirect environmental impacts of an infrastructure project deriving from the overall life-cycle of the different project components. Such indirect impacts are instead of key importance in order to assess the long-term sustainability of a transport infrastructure project. In the present study we suggest to overcome this limit by combining a conventional life-cycle assessment approach with standard transport cost-benefit analysis. The suggested methodology is tested upon a case study project related to the construction of a new fixed link across the Roskilde fjord in Frederikssund (Denmark). The results are then compared with those from a standard CBA framework. The analysis shows that indirect environmental impacts represent a relevant share of the estimated costs of the project, clearly affecting the final project evaluation. Additionally, they can significantly modify the weight of the different components of the overall project costs – evidently becoming a significant part of the estimated construction cost. Therefore, the suggested approach guarantees a higher quality of information thus providing decision makers with a more thorough insight of the environmental impact of the project.

Integrating Product and Technology Development: A Proposed Reference Model for Dual Innovation

Although dual innovation projects, defined in this article as the concurrent development of products and technologies, often occur in industry, these are only scarcely supported methodologically. Limited research has been done about dual innovation projects and their inherent challenges (e.g. managing dependencies) and opportunities (e.g. streamlining development). This paper presents five existing reference models for technology development (TD), which were identified via a systematic literature review, where their possible integration with product development (PD) reference models was investigated. Based on the specific characteristics desired for dual innovation projects, such as integrated product development and coverage of multiple development stages, a set of selection criteria was employed to select suitable PD and TD reference models. The integration and adaptation of the selected models has led to a proposed integrated reference model for dual innovation that is currently being instantiated in the context of an ongoing action research project.

Purpose: The aim of the research is to illustrate how companies can create competitive capabilities through integration of product design into the supply chain. In doing so the paper reveals the challenges and the opportunities that companies face when integrating product design and supply chain. Design/Methodology/Approach: The research is case based and focuses on six companies. Ten interviews were carried out in each of these with senior managers. The Resource-Based View (RBV) is utilised to put these empirical findings into a theoretical context. Findings: The findings reveal a range of opportunities and challenges when integrating product design and the supply chain and subsequently a step-by-step guide is developed to address these. Practical Implications: The research provides key recommendations to companies on how to create competitive capabilities by integrating product design into the supply chain. Originality/Value: This paper provides novel insights to both practitioners and researchers. For practitioners detailed recommendations are given on how they can maximise benefits through integrating product design into the supply chain. The RBV has been harnessed to highlight how integration needs to be balanced with the company's current resources and capabilities.
Integrating robust timetabling in line plan optimization for railway systems

The line planning problem in rail is to select a number of lines from a potential pool which provides sufficient passenger capacity and meets operational requirements, with some objective measure of solution line quality. We model the problem of minimizing the average passenger system time, including frequency-dependent estimates for switching between lines, working with the Danish rail operator DSB and data for Copenhagen commuters. We present a multi-commodity flow formulation for the problem of freely routing passengers, coupled to discrete line-frequency decisions selecting lines from a predefined pool. We show results directly applying this model to a Copenhagen commuter rail problem.

Integration of large-scale heat pumps in the district heating systems of Greater Copenhagen

This study analyses the technical and private economic aspects of integrating a large capacity of electric driven HP (heat pumps) in the Greater Copenhagen DH (district heating) system, which is an example of a state-of-the-art large district heating system with many consumers and suppliers. The analysis was based on using the energy model Balmorel to determine the optimum dispatch of HPs in the system. The potential heat sources in Copenhagen for use in HPs were determined based on data related to temperatures, flows, and hydrography at different locations, while respecting technical constraints. The Balmorel model was developed further in order to provide a better representation of HPs, for analysing the seasonal variations of COP (Coefficient of Performance), and to represent the difference in performance of HPs connected to either distribution or transmission networks. The optimization yields roughly 3500 FLH (full load hours) for the HPs connected to the DH distribution networks when considering a current scenario. In a zero carbon dioxide emission scenario expected in year 2025, approximately 4000 FLH, are achieved. In the case where HPs are connected to the DH transmission network at elevated temperatures, their operation decreases by roughly 1000 FLH. No significant impact was found when comparing fixed and varying operation characteristics of the HP.
Intentions to introduce electric vehicles in the commercial sector: A model based on the theory of planned behaviour

Light and heavy duty commercial vehicles are a cause of concern in urban areas because of their cumulative stress on the system in terms of air pollution, congestion, and noise. This cumulative stress is expected to increase with the expected growth in commercial vehicle movements. While electric commercial vehicles (ECVs) may provide a possible technological solution, the research on the market penetration of ECVs is scarce. This study proposes a comprehensive framework for understanding the motivations and barriers of small and medium-size firms to the introduction of ECVs in commercial vehicle fleets. The framework is based on the Theory of Planned Behaviour (TPB), and it is modelled with a structural equation model with latent variables. The model is estimated on the basis of 1443 responses from a large-scale survey in Austria, Denmark, and Germany. The results establish a linkage between the ECV procurement intentions, the TPB constructs (i.e., positive attitudes and subjective norms towards ECVs, familiarity with ECVs and perceived operational ease) and their relative importance. It also provides information regarding the relationship between the TPB constructs and the characteristics of the fleet manager as the individual decision maker, the industrial sector and the fleet management and tour pattern. Last, it provides insights regarding the transferability of the revealed TPB-ECV procurement intentions across industrial sectors and across countries. (C) 2016 Elsevier Ltd. All rights reserved.
Interactive Foresight Simulation
The Combined Simulation Approach (CSA) is a way to evaluate risks and address potential unforeseen problems in a more interactive way than what is often observed in practice in companies or sectors. The approach is based on a combination of scenario analysis and discrete-event computer simulation with which the strategies can be continuously developed. The contribution of this paper is to narrow the knowledge gap between strategic, tactical and operational levels of an organization. The paper demonstrates how it is possible to work proactively with both the breadth and depth of strategies using a Danish knowledge intensive company as an example. © 2015 Elsevier Inc. Inter-array cable routing optimization for big wind parks with obstacles

The optimization problem we study here consists in finding an optimal cable routing to connect a given number of offshore turbines to one (or more) offshore substation(s). Different constraints have to be respected, such as cable capacity, cable prices, crossing restrictions, limits on connections to substation(s), and possible presence of obstacles in the site. To solve this large-scale optimization problem we use a matheuristic approach, that is an hybridization of mathematical programming techniques and heuristics. First, a Mixed-Integer Linear Programming (MILP) model is defined. The MILP model is able to solve smaller instances to optimality but for large wind parks it fails in even finding a feasible solution. Therefore we investigate various matheuristics to handle this situation: the heuristics are used to decrease the number of variables in the optimization model by fixing some of them at each iteration. We propose and compare three different fixing strategy: “random fixing”, “distance based fixing” and “sector fixing”. Each of the three matheuristics has been tuned to find a proper trade-off between neighborhood size and solution time. Finally, we compare the solutions from the matheuristic framework with solutions from the initial MILP model on a number of real world instances, demonstrating the effectiveness of our approach when optimizing inter-array cable routing of big parks.

Internationale og nationale erfaringer for effekten af forskellige typer højklasset kollektiv transport og tæthed til stationer og standsningssteder

Landsplan direktivet for hovedstadsområdets planlægning (Fingerplan 2013, Miljøministeriet, 2013) fastlægger rammerne for den overordnede regionale udvikling samt kommunernes planlægning så hovedprincipperne i den overordnede fingerbystruktur videreføres. I blanding disse er en definition af en række stationer omkring hvilke størstedelen af byudviklingen bør ske, samt en definition af hvorledes stationsoplændene hertil fastlægges. Formål med projektet og rapporten er at identificere, vurdere samt give anbefalinger til forskellige alternative definitioner samt metoder til fastlæggelse af dels stationer samt dels stationsoplænde. Dette gøres på baggrund af, (i) erfaringer i international litteratur, (ii) de nyeste forskningserfaringer i dansk sammenhæng, samt(iii) egne undersøgelser af data indsamlet i forbindelse med transportvaneundersøgelsen kombineret med detaljerede netværksundersøgelser. Formålet med projektet er således baseret på internationale erfaringer samt nyeste forskning i national sammenhæng, at kortlægge forskellige karakteristika der påvirker brugen af stationer/stop samt giver forslag til alternative måder at, baseret på disse karakteristika, fastlægge relevante stationer/stop.

Inter-organizational cooperation for greener products and services

The business world experiences an increasing attention to sustainability topics. In response to their stakeholders’ concerns or following their own aspirations, more and more companies develop their approaches to sustainability. Life-cycle thinking recommends companies to integrate their sustainability strategies into a value chain perspective in order to avoid burden shifts from one life-cycle stage to another. Certain decisions impacting products’ and services’ life-cycle may be taken at a given company, while others are likely to be beyond the direct control of the company and require to be managed through inter-organizational interactions. Numerous scholars call for increased cooperation between companies on green issues. On the other hand, the business world experiences a current development in sustainability approaches deeply rooted in inter-organizational cooperation such as circular business strategies, green supply chain initiatives, and target setting on a value chain level. Current literature on green management reveals that cooperation practices across companies on green issues are still rare, that implementing cooperation practices is challenging and that there is a need for shift in focus from why companies should develop sustainability strategies to how they may implement the latter. In our on-going study, we base our approach on the contingency theory and build on inputs from academia to develop a conceptual management model aimed at supporting the discussion and reflection for a given company about its current or possible cooperation practices with other companies, in a context of greener products or services. Moreover, this model is elaborated to support identifying the existence of companies’ archetypes towards inter-organizational cooperation. The up-to-date model is elaborated around three main areas: factors influencing cooperation practices, cooperation approaches and cooperation activities.

Intervention Framework to Support Employee-Driven Innovation Between R&D and Manufacturing Department

This paper is exploring the area of employee-driven innovation (EDI) and describes how we in our research project have developed and tested a framework for initiating employee participation between R&D and manufacturing department. EDI refers to the generation and implementation of significant new ideas, products and processes originating from employees who are not assigned to this task [Kesting and Ulhøi 2010]. EDI is not a well-documented field of research in the general innovation literature [Sørensen and Wandahl 2012], and there is limited descriptions about how EDI is initiated and supported in product innovation. This paper aims at bridging the gap by presenting a novel and state of art intervention framework to initiate employee-driven initiatives and accommodate the need to demonstrate how EDI can be applied in future product development processes. The framework is unique in the sense that it delivers a pragmatic approach to research and business practitioners promoting EDI. The intervention framework is developed as a part of a research project study called “Employee involvement in product innovation” at the Technical University of Denmark, and is currently being tested in an on-going study to further validate the framework. Innovation capabilities are today a key imperative in order survive in the ever growing competitive landscape in both public and private organizations [Gressgård et al. 2014].

Being widely adopted in the Scandinavian countries, the notion of employee involvement is considered a way for organizations to achieve the responsiveness needed in a hypercompetitive world [Riordan et al. 2005]. As workplaces become more complex and employee’s increasingly demands more satisfying jobs, employee involvement becomes a way for companies to attract and retain the best human talents [Kesting and Ulhøi 2010]. It is argued that companies should not restrict themselves to relying exclusively on R&D employees, but also recognize that manufacturing employees possess abilities for innovation [Heyrup2010]. Several other theories, such as high-involvement innovation share the conviction that innovation is a team-discipline and rely on participation and involvement of people outside R&D [Bessant and Caffyn 1997]. The underlying assumption of EDI is that all employees have hidden innovative potential that can be made visible, recognized and exploited to the benefit of both the company and its employees [Kesting and Ulhøi 2010].

Innovation is originally defined as “novelty creating economic value” by Schumpeter in 1934, but in terms of EDI and workspace learning, other values could mean employability, welfare in working life, learning culture and innovation [Heyrup 2010]. Some of the benefits of turning towards EDI thinking can be described as: • Higher levels of employee involvement are positively associated with increased financial performance of a company [Riordan et al. 2005]. • Increased employee autonomy has positive impacts on employee satisfaction and retention of good employees [Kesting and Ulhøi 2010].

Happy and satisfied employees are more productive and have fewer sick days [LO 2008]. • Increased focus on radical innovation. Compared to user-driven innovation, EDI can breed more radical innovative thinking, where user-driven innovation tends to focus on sub-optimization and incremental design changes [Kesting and Ulhøi 2010]. • Involving employees improve collaboration and knowledge sharing to optimise processes and product development. It is considered a key success factor in complex environments where networking, fast renewal and innovation are central competitive factors [Alasoini et al. 2013]. • It can generate a flow of additional information and tacit knowledge from employees to point out opportunities that management cannot [Kesting and Ulhøi 2010]. With a long list of known benefits from EDI, one might wonder why it is not implemented everywhere? The list of EDI obstacles includes [Sørensen and Wandahl 2012]: • No incentives or motivation to engage in development and innovation activities • Management focus is on production tasks, hence no management support • No systematic approach to facilitate idea generation and knowledge-sharing • Organisational culture • Development and innovation are based on few individuals. The company culture is one of the main barriers, and supports the management truism; that “culture eats strategy for breakfast”. The formality of the R&D organisational structure becomes a limitation when trying to make organisational changes to support the product development process. Well knowing that the innovative capabilities of a company is also determined by a complex set of different aspects such as the culture and mind-set of the employees in all levels of the organization [Sørensen and Wandahl2012], this project investigates how to initiate an organisational change to support the ideation of employee participation in two case companies. The overall purpose of this paper is to present, develop and test participatory methods for initiating employee-driven innovation across R&D and manufacturing employees.

Ja, cykelhjelmen beskytter!
Cykelhjelmens trafiksikkerhedsmæssige effekt har været genstand for omfattende debat. Baseret på en gennemgang af videnskabeligt publicerede resultater har to australske forskere lavet en metaanalyse med det formål at skabe et videnskabeligt baseret overblik over den eksisterende viden. Samlet viser metaanalysen, at anvendelse af cykelhjelm har en markant positiv effekt på hovedskader og ansigtsskader blandt tilskadekomne cyklister.

Joint overbooking and seat allocation for fare families
Revenue Management Systems (RMS) traditionally solve the seat allocation problem separately from the overbooking problem. Overbooking is managed by inflating the authorization levels obtained from seat allocation by various heuristics. This approach although suboptimal, is necessitated because of the complexity and dimensionality of the Dynamic Program (DP), which prohibits computation for realistic size problems.
We review several DP models developed for seat-allocation and overbooking over a time span of 40 years, reflecting changed business environments. In this report we link these models together by means of two transformations: The marginal revenue transformation of Fiig et al. [2010] and the equivalence charging scheme of Subramanian et al. [1999]. These transformations enable us to transform the joint seat allocation and overbooking problem for fare family fare structures into an equivalent independent demand model, which is readily solved. The resulting availability control can easily be implemented in existing RMS

Kan mobiltelefonen bidrage til bedre trafiksikkerhed?
Mobiltelefonen er kommet for at blive, og rigtige mange bilister benytter den, mens de kører bil. Hvis mobiltelefonens funktioner kan udnyttes til fordel for trafiksikkerheden, rummer det derfor et stort potentiale, fordi det principielt er muligt at nå ud til mange bilister med begrænsede ressourcer. Som et første skridt på vejen har et ekspertpanel evalueret forskellige apps for at afdække deres trafiksikkerhedsforbedrende potentiale.

Knowledge sharing behavior and intensive care nurse innovation: the moderating role of control of care quality

Aims
This study investigates the influence of intensive care unit nurses' knowledge sharing behaviour on nurse innovation, given different conditions of care quality control.

Background
Health-care organisations face an increasing pressure to innovate while controlling care quality. We have little insight on how the control of care quality interacts with the knowledge sharing behaviour of intensive care nurses to affect their innovative behaviours.

Methods
We developed a multi-source survey study of more than 200 intensive care nurses at 22 intensive care units of 17 Danish hospitals. Two versions of the questionnaire were used – one designed for nurse employees and the other for the managing nurse(s). An ordinary least squares regression analysis was used to test the hypotheses.

Results
Different aspects of knowledge sharing affect innovation differently, depending on the strength of the control of care quality within the unit.

Conclusions
The increasing pressures to implement the control of care quality and innovate may be conflicting, unless handled properly.

Implications for nursing management
Process control at intensive care units should be loosened, when personal interaction between intensive care nurses is encouraged to stimulate nurse innovations. Alternatively, managers may develop a climate where helping others, especially with younger colleagues, offsets the negative effects of strong process control.

Knowledge Sharing, Control of Care Quality, and Innovation in Intensive Care Nursing

This study investigates the influence of nurse knowledge sharing behavior on nurse innovation, given different conditions of control of care quality within the intensive care unit (ICU). After conducting a number of interviews and a pilot study, we carried out a multi-source survey study of more than 200 nurses employed in 22 ICUs at 17 Danish hospitals. Overall, we find that knowledge sharing among individual ICU nurses has a positive impact on their innovation. Meanwhile, strong control of care quality makes this positive impact less effective. However, different aspects of knowledge sharing affect innovation differently, depending on the strength as well as type of control of care quality within the unit. Healthcare organizations face an increasing pressure to innovate while controlling and accounting for care quality. This study demonstrates that the increasing pressures to implement control of care quality and innovate may be conflicting, unless handled properly.

Land Use in LCIA: an absolute scale proposal for Biotic Production Potential

Environmental impacts caused by land occupation and transformation have been bypassed in many LCA studies due to soils’ multifunctionality and the interconnectedness between the ecosystem services they provide. These inherent modelling complexities have traditionally forced LCA practitioners to content with a mere quantification of Land Use (LU), as surface area and duration (in m² or ha and years) appropriated by humans, without further analysis of the impact pathways derived from those land uses. Milà i Canals established the first comprehensive, basic framework for taking soil quality aspect into LCIA that reached acceptance among the LCA community. Through contributions from UNEP-SETAC’s special task force on LU, great progress has ensued in developing further such LCIA. Building on the latest proposal by Koellner et al. and with the aim of bringing the Planetary Boundaries thinking into LCA, the present study proposes a single absolute scale for the midpoint impact category (MIC) of Biotic Production Potential (BPP). It is hypothesized that, for an ecosystem in equilibrium (where NPP equals decay), such an ecosystem has reached the maximum biotic throughput subject to site-specific conditions and no externally added inputs. The original ecosystem (or Potential Natural Vegetation) of a certain land gives then the maximum BPP with no additional, downstream or upstream, impacts. This Natural BPP is proposed as the maximum BPP in a hypothetical Absolute Scale for LCA’s Land Use framework. It is argued that this maximum BPP is Nature’s optimal solution through evolution-adaptation mechanisms, which provides the maximum matter throughput subject to the rest of environmental constraints (without further impacts). As a consequence, this scale rises a Land Use Optimality Point that suggests the existence of a limit regarding the maximization of divergent objectives with bioenergy. It will be attempted to model that beyond this point, and for the land available within a country, if the objective of Climate Change mitigation through bioenergy is further maximized, then the Fossil Fuel displacing objective will decrease, and vice versa.

Latent lifestyle and mode choice decisions when travelling short distances

In the quest for sustainable travel, short distances appear the most amenable to curbing the use of the automobile. Existing studies about short trips evaluate the potential of shifting from the automobile to sustainable travel options while considering the population as homogeneous in its preferences and its tendency to accept these alternative travel options as realistic. However, this assumption appears quite unrealistic and the current study offers a different perspective: the mode choices when travelling short distances are likely related to lifestyle decisions. Short trip chains of a representative sample of the Danish population in the Copenhagen Region were analysed, and more specifically a latent class choice model was estimated to uncover latent lifestyle groups and choice specific travel behaviour. Results show that four lifestyle groups are identified in the population: car oriented, bicycle oriented, public transport oriented and public transport averse. Each lifestyle group has specific perceptions of travel time (with extremely different rates of substitution between alternative travel modes), transfer penalties in public transport trip chains, weather influence (especially on active travel modes), and trip purpose effect on mode selection. Consequently, when thinking about measures to increase the appeal of sustainable travel options, decision-makers should look at specific individuals within the population and more sensitive individuals to comfort and level-of-service improvements across the lifestyle groups.

LCA of pork products & evaluation of alternative super-chilling techniques
This LCA study has two aims: 1) The environmental assessment of Danish pork products (Danish Landrace breed): The purpose is to put the pork production system into perspective and to identify the relative contribution of different life cycle stages; 2) The comparative assessment of alternative after cooling technologies, which affect the products’ shelf life: The purpose is to identify the technology leading to least environmental impacts in a life cycle perspective; also to facilitate a benchmarking of these technologies relative to existing after-cooling approaches i.e. freezing.

Lean as a Tool for Systematic Employee based Improvement of Psychosocial Factors in Hospitals

The work pressure in hospital is growing due to an increase in patient demands and economic constraints. Problems in communication and coordination often constitute important factors for the increased pressure. This paper describes the P-lean methodology which can facilitate solutions to such problems. The methodology builds on lean focusing on value stream mapping (VSM) in particular. Groups of employees carry out VSM of selected processes, follow up with the collection of data on the processes and develop suitable solutions. The data from testing of the methodology test shows that VSM, in particular, provides new insights, which help employees to identify and implement improvements. Hospital wards implementing the methodology need some external facilitator assistance. Communication and coordination across wards in the hospital are an important issue but proved to be difficult also with this methodology.

Learning facilitating leadership

This paper explains how engineering students at a Danish university acquired the necessary skills to become emergent facilitators of organisational development. The implications of this approach are discussed and related to relevant viewpoints and findings in the literature. The methodology deployed for this paper is empirical and conceptual. A specific facilitation project carried out by six international engineering students is presented. The importance of combining cognitive, emotional and synergistic skills is highlighted on the basis of this example, the authors' extensive experience in teaching facilitation and the literature. These types of skills are most effectively acquired by combining conceptual lectures, classroom exercises and the facilitation of groups in a real-life context. The paper also reflects certain 'shadow sides' related to facilitation observed by the students and discussed in the literature. The educational process description and reflections presented in this paper can help university staff and mentors in public and private organisations to adopt interactive methods for education and training. A brief overview of the methods used is included in the Appendix. By connecting the literature, the authors' and engineering students’ reflections on facilitator skills, this paper adds value to existing academic and practical discussions on learning facilitating leadership.

This user-friendly book introduces biochar to potential users in the professional sphere. It de-mystifies the scientific, engineering and managerial issues surrounding biochar for the benefit of audiences including policy makers, landowners and farmers, land use, agricultural and environmental managers and consultants, industry and lobby groups and NGOs. The book reviews state-of-the-art knowledge in an approachable way for the non-scientist, covering all aspects of biochar production, soil science, agriculture, environmental impacts, economics, law and regulation and climate change policy. Chapters provide 'hands-on' practical information, including how to evaluate biochar and understand what it is doing when added to the soil, how to combine biochar with other soil amendments (such as manure and composts) to achieve desired
outcomes, and how to ensure safe and effective use. The authors also present research findings from the first coordinated European biochar field trial and summarize European field trial data. Explanatory boxes, infographics and concise summaries of key concepts are included throughout to make the subject more understandable and approachable.

Life Cycle Assessment of Functionally Enhanced Polymers-Engineered Nanomaterials or Conventional Additives?
Engineered nanomaterials, where at least one dimension is within 1-100 nm, are produced and used in many consumer products, with the purpose of enhancing specific material properties (e.g., in plastic products). Conventionally, organic and inorganic non-engineered nanomaterial additives are also used to enhance material properties. The aim of this study is to perform life cycle assessments (LCAs) on 5 polymer products (polypropylene air-conditioner part for cars, polypropylene garden chair, polypropylene small electrical box for houses, polyvinylchloride-wood outdoor flooring and polystyrene insulation panels for buildings). Antibacterial, ultraviolet ray protection or flame retardancy properties of these products have been improved through the addition of either Ag, ZnO or Mg(OH)2 engineered nanomaterials, or conventional organic/inorganic polymer additives. The study also presents new industrial production inventories of the considered engineered nanomaterials as well as the quantification of potential changes in impacts when the LCA functional unit is adjusted according to material functionality (antibacterial, ultraviolet-protection and flame retardancy). The LCA results show that in all cases the products with engineered nanomaterials generate higher potential environmental impacts than products with conventional additives. However, when considering the improved material functionality results differ more. The polyvinylchloride-wood outdoor flooring and polystyrene insulation panels for buildings with engineered nanomaterials perform better than with the use of conventional additives, while the polypropylene products with engineered nanomaterials have slightly higher environmental impacts than products with conventional additives. In the case of polypropylene small electrical box the needed large content of micro-Mg(OH)2 makes the engineered nanomaterial case far less favourable, but if Mg(OH)2 substitutes halogenated flame retardants the potential toxicological impacts are shown to be significantly lower. This study shows that the consideration of enhanced material functionality in LCA can favour some of the engineered nanomaterial based products, versus conventional additives, by reflecting the potential increase in use quality and potentially the use time. Also in this study, based on assumed release amounts, freshwater ecotoxicity caused by engineered nanomaterial release from products is quantified showing a novel approach.

Life cycle assessment of onshore and offshore wind energy - from theory to application

This study aims to assess the environmental impacts related to the provision of 1 kWh to the grid from wind power in Europe and to suggest how life cycle assessment can inform technology development and system planning. Four representative power plants onshore (with 2.3 and 3.2 MW turbines) and offshore (4.0 and 6.0 MW turbines) with 2015 state-of-the-art technology data provided by Siemens Wind Power were assessed. The energy payback time was found to be less than 1 year for all technologies. The emissions of greenhouse gases amounted to less than 7 g CO2-eq/kWh for onshore and 11 g CO2-eq/kWh for offshore. Climate change impacts were found to be a good indicator for overall hotspot identification however attention should also be drawn to human toxicity and impacts from respiratory inorganics. The overall higher impact of offshore plants, compared to onshore ones, is mainly due to larger high impact material requirements for capital infrastructure. In both markets the bigger turbines with more advanced direct drive generator technology is shown to perform better than the smaller geared ones. Capital infrastructure is the most impactful life cycle stage across impacts. It accounts for more than 79% and 70% of climate change impacts onshore and offshore respectively. The end-of-life treatment could lead to significant savings due to recycling, ca. 20-30% for climate change. In the manufacturing stage the impacts due to operations at the case company do not exceed 1% of the total life cycle impacts. This finding highlights the shared responsibility across multiple stakeholders and calls for collaborative efforts for comprehensive environmental management across organizations in the value chain. Real life examples are given in order to showcase how LCA results can inform decisions, e.g. for concept and product development and supply chain management. On a systems level the results can be used by energy planners when comparing with alternative energy sources. (C) 2016 Elsevier Ltd. All rights reserved.

Life cycle assessment of stormwater management in the context of climate change adaptation

Expected increases in pluvial flooding, due to climatic changes, require large investments in the retrofitting of cities to keep damage at an acceptable level. Many cities have investigated the possibility of implementing stormwater management (SWM) systems which are multi-functional and consist of different elements interacting to achieve desired safety levels. Typically, an economic assessment is carried out in the planning phase, while environmental sustainability is given little or no attention. In this paper, life cycle assessment is used to quantify environmental impacts of climate change adaptation strategies. The approach is tested using a climate change adaptation strategy for a catchment in Copenhagen, Denmark. A stormwater management system, using green infrastructure and local retention measures in combination with planned routing of stormwater on the surfaces to manage runoff, is compared to a traditional, sub-surface approach. Flood safety levels based on the Three Points Approach are defined as the functional unit to ensure comparability between systems. The adaptation plan has significantly lower impacts (3-18 person equivalents/year) than the traditional alternative (14-103 person equivalents/year) in all analysed impact categories. The main impacts are caused by managing rain events with return periods between 0.2 and 10 years. The impacts of handling smaller events with a return period of up to 0.2 years and extreme events with a return period of up to 100 years are lower in both alternatives. The uncertainty analysis shows the advantages of conducting an environmental assessment in the early stages of the planning process, when the design can still be optimised, but it also highlights the importance of detailed and site-specific data.

Life cycle human health impacts of 875 pesticides

Purpose
Residues in field crops grown and harvested for human consumption are the main contributor to overall human exposure toward agricultural pesticides for the general population. However, exposure from crop residues is currently not considered in life cycle assessment practice. We therefore present a consistent framework for characterizing human toxicological impacts associated with pesticides applied to agricultural crops in the frame of life cycle impact assessment based on state-of-the-art data and methods.

Methods
We combine a dynamic multicrop plant uptake model designed for evaluating human exposure to residues for a wide range of pesticide-crop combinations with latest findings of pesticide dissipation kinetics in crops and post-harvest food processing. Outcome is a set of intake fractions and characterization factors for 875 organic pesticides and six major food crops along with specific confidence intervals for each factor.

Results and discussion
Intake fractions aggregating exposure via crop residues and exposure via fractions lost to air and soil for pesticides applied to agricultural crops vary between $10^{-8}$ and $10^{-1}$ kg intake per kilogram applied as a function of pesticide and crop. Intake fractions are typically highest for lettuce and tomato and lowest for potato due to differences in application times before crop harvest and soil as additional barrier for uptake into potato tubers. Uncertainty in intake fractions is mainly associated with dissipation dynamics in crops, where results demonstrate that using pesticide- and crop-specific data is crucial. Combined with the uncertainty in effect modeling, characterization factors per pesticide and crop show squared geometric mean standard deviations ranging from 38 to 15,560 over a variability range across pesticide-crop combinations of 10 orders of magnitude.

Conclusions
Our framework is operational for use in current life cycle impact assessment models, is made available for USEtox, and closes an important gap in the assessment of human exposure to pesticides. For ready use in life cycle assessment studies, we present pesticide-crop combination-specific characterization factors normalized to pesticide mass applied and provide default data for application times and loss due to post-harvest food processing. When using our data, we emphasize the need to consult current pesticide regulation, since each pesticide is registered for use on certain crops only, which varies between countries.

General information
Lignocellulosic residues for production of electricity, biogas or second generation biofuel: A case study of technical and sustainable potential of rice straw in Mali

Biomass from agricultural residues, especially lignocellulosic biomass, is not only seen as a sustainable biomass source for the production of electricity, but increasingly as a resource for the production of biogas and second generation biofuel in developing countries. Based on empirical research in an irrigated rice-growing area, Office du Niger, in Mali, this article builds scenarios for the sustainable potential of rice straw. The paper concludes that there is great uncertainty regarding the size of the sustainable resources of rice straw available for energy, but that the most likely scenario estimates a resource of about 120,000 t, which would permit up to three 5 MWel rice straw-fuelled power plants. Based on the findings from the empirical studies, the article further suggests that recently published research on the potential of rice straw in a number of African countries seems first to underestimate the uncertainty of resource assessments, and secondly to overestimate the resources available for energy production, mainly due to optimistic residue-to-product ratios and availability factors.© 2016 Elsevier Ltd. Limitations and opportunities of combining Cradle to Grave and Cradle-to-Cradle approaches to support the circular economy

Both Life Cycle Assessment (LCA) with its “Cradle to Grave” approach and the Cradle to Cradle® (C2C) design framework based on the eco-effectiveness concept can support the implementation of circular economy. Based on the insights gained in the packaging sector, we perform a Strengths, Weaknesses, Opportunities, and Threats (SWOT) analysis of the combined use of LCA and “C2C tools”, i.e. the C2C design protocol and the C2C certified TM product standard, in the implementation of circularity strategies at the product level. Moreover, we discuss the challenges which need to be addressed in order to move from a relative to an absolute environmental sustainability perspective at the company level, and define a framework for implementing circularity strategies at the company level, considering an absolute environmental sustainability perspective and the business dimension.

Load-shift incentives for household demand response: Evaluation of hourly dynamic pricing and rebate schemes in a wind-based electricity system

Applying a partial equilibrium model of the electricity market we analyse effects of exposing household electricity customers to retail products with variable pricing. Both short-term and long-term effects of exposing customers to hourly spot market prices and a simpler rebate scheme are analysed under scenarios with large shares of wind power in a Danish case study. Our results indicate strategies that could be favourable in ensuring high adoption of products and efficient response by households. We find that simple pricing schemes, though economically less efficient, could become important in an early phase to initialise the development of household demand response. At a later point, when long-term dynamics take effect, a larger effort should be made to shift consumers onto real-time rates, and an increased focus on overall adoption of variable pricing will be required. Another finding is that demand response under variable pricing makes wind power more valuable. These gains in value reduce the need for support, and could be redistributed in further support of demand response.

Local control on precipitation in a fully coupled climate-hydrology model

The ability to simulate regional precipitation realistically by climate models is essential to understand and adapt to climate change. Due to the complexity of associated processes, particularly at unresolved temporal and spatial scales this continues to be a major challenge. As a result, climate simulations of precipitation often exhibit substantial biases that affect the reliability of future projections. Here we demonstrate how a regional climate model (RCM) coupled to a distributed hydrological catchment model that fully integrates water and energy fluxes between the subsurface, land surface, plant cover, and the atmosphere, enables a realistic representation of local precipitation. Substantial improvements in simulated precipitation dynamics on seasonal and longer time scales is seen for a simulation period of six years and can be attributed to a more complete treatment of hydrological sub-surface processes including groundwater and moisture feedback. A high degree of local influence on the atmosphere suggests that coupled climate-hydrology models have a potential for improving climate projections and the results further indicate a diminished need for bias correction in climate-hydrology impact studies.

Local sustainable district energy cases from across Europe

In the progRESsHEAT project, six local cases are analysed. The main objective of the progRESsHEAT project is to support policy makers and public authorities at local, regional and national level in the development and implementation of integrated strategies and policies to enforce the use of renewable and efficient heating and cooling solutions in their regions. The main pillar of the strategy development process are local case studies for six municipalities. The goal of these case studies is to develop heating and cooling strategies through a profound analysis of (1) heating and cooling demands with respect to future developments, (2) long-term potentials of renewable energies and waste heat in the regions, (3) barriers & drivers and (4) a model based assessment of policy intervention in scenarios up to 2050 together with the authorities. For this purpose we apply a geographic information system (GIS) and map the energy demands based on modelling of buildings and industry, the potential RE sources (including biomass, solar, geothermal, etc.) as well as waste heat sources and the existing energy production plants locally for each municipality. The district energy system of each municipality is then modelled in a coherent energy system analysis tool (EnergyPRO) which combines the detailed demand side modelling with the geographical overview of the resources and the existing production plants. The costs of providing district energy is then entered into a cost curve tool where the cheapest solution is found, depending on the location and type of building, comparing 1) district energy costs to 2) costs of increased energy efficiency and 3) costs of individual energy solutions. Thereby, the most cost effective solutions to increase RES heating and cooling at local level are identified. Recent results from the local case studies will be presented, illustrating business cases for district heating in different regions in EU as well as the key success factors and main challenges and barriers for increased efficiency and sustainability of the European heating and cooling sector.

Long-term research challenges in wind energy – a research agenda by the European Academy of Wind Energy

The European Academy of Wind Energy (eawe), representing universities and institutes with a significant wind energy programme in 14 countries, has discussed the long-term research challenges in wind energy. In contrast to research agendas addressing short- to medium-term research activities, this eawe document takes a longer-term perspective, addressing the scientific knowledge base that is required to develop wind energy beyond the applications of today and tomorrow. In other words, this long-term research agenda is driven by problems and curiosity, addressing basic research and fundamental knowledge in 11 research areas, ranging from physics and design to environmental and societal aspects. Because of the very nature of this initiative, this document does not intend to be permanent or complete. It shows the vision of the experts of the eawe, but other views may be possible. We sincerely hope that it will spur an even more intensive discussion worldwide within the wind energy community.
Mainstreaming life cycle thinking through a consistent approach to footprints

Over recent years, footprints have emerged as an important means of reporting environmental performance. Some individual footprints have become quite sophisticated in their calculation procedures. However, as an overall class of environmental metrics they have been poorly defined, having a variety of conceptual foundations and an unclear relationship to LCA. The variety and sometimes contradictory approaches to quantification have also led to confusing and contradictory messages in the marketplace which have undermined their acceptance by industry and governments. In response, a task force operating under the auspices of the UNEP/SETAC Life Cycle Initiative project on environmental Life Cycle Impact Assessment has been working to develop generic guidance for developers of footprint metrics. The initial work involved forming a consensual position on the difference between footprints and existing LCA impact category indicators.

In short, footprints are deemed to have a primary orientation toward society and nontechnical stakeholders and report only on selected topics of concern. On the other hand, LCA impact category indicators have a primary orientation toward technical stakeholders and report in relation to a larger framework designed for comprehensive evaluation of environmental performance and trade-offs. The task force has also developed a universal footprint definition. In parallel to Area of Protection, we introduce Area of Concern. In the same way that LCA uses impact category indicators to assess impacts that follow a common cause-effect pathway toward Areas of retoction, footprint metrics address Areas of Concern. The critical difference is that Areas of Concern are defined by the interests of stakeholders in society rather than the LCA community. In addition, Areas of Concern are stand-alone and not part of a framework intended for comprehensive environmental performance assessment. Accordingly, footprints are universally defined as metrics used to report life cycle assessment results addressing an Area of Concern.

Management of business process design in global implementation of enterprise resource planning systems

Investments in global enterprise resource planning (ERP) systems are typically carried out as a part of the globalization process in multinational corporations (MNCs). Global ERP systems support integration and control in MNCs in an important way by establishing a common language across an MNC. As process and data standardization are among the primary drivers of ERP consolidation efforts, business process design is an important concern when implementing global ERP systems. This PhD study addresses three research questions that develop understanding, support, and improvement of the practice of business process design in the course of a global ERP implementation in MNCs. In light of existing theoretical and practical challenges, the research questions focus on three business process management (BPM) capabilities: alignment, governance, and method. Drawing on extensive literature reviews and findings from case studies in nine organizations, the study addresses the three prescriptive research questions through five descriptive studies.

First, by deploying alternative theories, this study explores the strategic, institutional, organizational, and relational factors that influence business process design, and particularly process standardization, in an MNC. Second, the study investigates implications of process standardization for the choice of ERP architecture in MNCs. The findings indicate the moderating impact of process standardization on a global ERP systems total cost of ownership and its support for control and coordination. Third, having identified the factors that influence process standardization in MNCs, the study investigates the alignment between process standardization and an MNC's international management strategy and
indicates that process standardization as a centralizing coordination mechanism better fits MNCs structured for global integration compared to those seeking local responsiveness. The study develops conditions of fit between structural elements characterizing an MNC’s international management strategy and process standardization.

Fourth, seeking governance mechanisms enabling business process design, the study explores collaborations between BPM and IT management functions and suggests the need for horizontal integration between the two functions in support of business–IT alignment. In addition, the study associates the direction of integration with the role of IT. Fifth, in search of a method enabling integrated business process design, the study investigates diverse views on enterprise architecture (EA) and various applications of enterprise architecture management (EAM) in organizations. The findings are classified as a taxonomy of EAM applications in organizations based on EA scope.

Drawing on findings from descriptive studies, the PhD study clarifies the criticality of business process design in the course of a global ERP implementation by explaining the impact of strategic, institutional, organizational, and relational contexts on process standardization on the one hand, and the importance of process standardization for reducing ERP total cost of ownership and its deployment as an integrative mechanism on the other. The study concludes that business process design in the course of a global ERP implementation can be supported by aligning decision making on process standardization with corporate international management strategy and structural characteristics. Furthermore, business process design can be supported by establishing permanent central governance for BPM and horizontally integrating the BPM function with the IT function at the strategic and operational levels. Business process design in the course of a global ERP implementation can be improved by adopting EAM as a methodology that enables integrated design of business processes and IT systems in alignment with business strategy.

Measuring and developing Communities of Practice in a blood analysis unit

Introduction:
Knowledge sharing is essential to develop operational efficiency and quality. However, knowledge sharing is difficult to achieve due to 24-7 shifts, patient contact and little time for meetings. The theory of communities of practice (CoP) proposes an alternate approach to knowledge sharing. A CoP is a social community formed around a practice (e.g. ICU nursing) which induce a propensity to share experiences and thereby constitute knowledge sharing.

CoP was conceived as a descriptive construct but has gained popularity and is found to improve practice performance, but knowledge about developing and measuring CoP is lacking.

We propose a method to measure and develop CoP and the method is tested in a blood analysis unit at 'Nordsjællands Hospital' in Denmark.

Material and method:
The practice was operationalized narrowly as employees performing a specific maintenance task. A questionnaire was developed based on a CoP literature review. Using the ‘think aloud’ method the questionnaire was tested with practitioners investigating if questions were decoded correctly and triggered the desired mental image.

CoP level was measured at baseline and at follow-up (seven weeks after the intervention). Interventions were initiated just after baseline measurement.

The following CoP developing interventions took place: The practice was chosen due to a high frequency and recurring problems. A voluntary CoP facilitator was identified. She then invited her colleagues to participate in the CoP and arranged CoP meetings. The ‘Event Effect Method’ was used to control for effect modifiers by identifying events both part and not part of the intervention and estimating their effect on CoP.

Result:
Results will be available for the conference. A response rate of 50-60% is expected. We expect increased CoP activity in the form of increased levels of reported knowledge sharing and common problem solving and increased amount of improvement suggestions.

Conclusion:
We hope to conclude that the questionnaire identified statistically significant changes (p<0,05). We expect few effect
modifiers were identified and assessed as having no impact on the measured CoP. We expect the change in CoP level to correspond with intervention associated events and interventions are concluded to have produced the desired effect, and that the questionnaire measures this change.

**Measuring the rebound effect with micro data: A first difference approach**
We provide estimates of the rebound effect for car transport in Denmark, using a rich data set with individual household data on car use, fuel efficiency, and car as well as household characteristics. A demand model is estimated in first differences; the availability of households in the sample that replaced their car during the period of observation combined with information on their driving behaviour before and after the car switch allows us to identify the rebound effect. Endogeneity is taken into account by using appropriate instruments. Results include the following. First, we reject the ‘conventional’ formulation in which only fuel cost per kilometre matters. Second, the selection equation confirms that higher fuel prices induce households to switch car. Third, the results suggest the presence of a rebound effect that is on the lower end of the estimates available in the literature. Specifically, our best estimate of the rebound effect is some 7.5-10%. Fourth, the fuel price sensitivity of the demand for kilometres appears to be declining with household income, but we do not find a significant impact of income on the rebound effect. Finally, simulation results indicate that the small rebound effect and changes in car characteristics in response to higher fuel prices imply that - compared to the reference scenario - higher fuel prices lead to a substantial reduction in both the demand for kilometres and in demand for fuel.

Medarbejderinddragelse i produktinnovation: Hvorfom MIPI? Fordele og forudsætninger

Dette hæfte beskriver hvilke fordele der kan opnås ved at inddrage medarbejdere fra produktionen, samt hvilke forudsætninger der ligger til grund. Hæftet skaber grundlaget for at benytte hæfte 2, som giver en pejling af dit udgangspunkt for at inddrage medarbejdere og dernæst hæfte 3, som præsenterer konkrete metoder til medarbejderinddragelse. Som illustreret i figuren er hæfterne værktøjer til at afklare og afstemme hvordan medarbejderne kan inddrages i produktinnovation i netop din virksomhed.

Formålet med MIPI hæfterne er at oplyse og hjælpe virksomheder med at benytte medarbejderinddragelse i produktinnovation. I hæfterne findes information og inspiration, samt konkrete arbejdsmetoder til at initiere medarbejderinddragelse. Hæfterne er rettet imod ledelsen og projektledere i danske fremstillingsvirksomheder med egen produktudvikling.

Medarbejderinddragelse i produktinnovation: Hvad er jeres udgangspunkt? En diagnose af virksomheden

Dette hæfte hjælper med at finde jeres udgangspunkt for at inddrage produktionsmedarbejdere i produktinnovation. Det gøres ved at udføre en diagnose i tre trin, som omhandler virksomhedens: 1) udviklingsarbejde, 2) produkt og 3) produktionsmedarbejdere. Ved at udføre diagnosen stiller man sig selv nogle fundamentale spørgsmål om sin virksomhed, og når frem til, hvordan man kan begynde medarbejderinddragelse. I diagnosen svarer man på spørgsmål...
ved at vælge den farve som passer bedst til jeres virksomhed. Der skal derfor findes farver for hvert trin i diagnosen. På
baggrund af diagnosen, og de farver der er valgt, får man sidst i hæftet anbefalet nogle metoder til
medarbejderinddragelse. Metoderne er beskrevet i hæfte 3.

Formålet med MIPI hæfterne er at oplyse og hjælpe virksomheder med at benytte medarbejderinddragelse i produktinnovation. I hæfterne findes information og inspiration, samt konkrete arbejdsmetoder til at initiere medarbejderinddragelse. Hæfterne er rettet imod ledelsen og projektledere i danske fremstillingsvirksomheder med egen produktudvikling.

Medarbejderinddragelse i produktinnovation: Hvordan gør man? Metoder til inddragelse

Dette hæfte beskriver 9 metoder til hvordan virksomheder kan inddrage produktionsmedarbejdere i produktinnovation. Metoderne er blevet udviklet og testet i samarbejde med danske produktionsvirksomheder. Metoderne understøtter alle samarbejde og kommunikation, som et middel til at opnå produktinnovation. Metodebeskrivelserne er rettet imod projektledere i enten udvikling eller produktion, som ønsker at få input til produktinnovation.

Formålet med MIPI hæfterne er at oplyse og hjælpe virksomheder med at benytte medarbejderinddragelse i produktinnovation. I hæfterne findes information og inspiration, samt konkrete arbejdsmetoder til at initiere medarbejderinddragelse. Hæfterne er rettet imod ledelsen og projektledere i danske fremstillingsvirksomheder med egen produktudvikling.

Mentorship of expatriates in transnational companies

Purpose:
Due to a number of reported failures of expatriation assignments, a growing body of literature is exploring the possible roles of mentors in supporting expatriates in critical phases while working in another culture. The purpose of this paper is to expand upon the research of mentoring based on a literature review and an empirical study of mentoring expatriates in three transnational companies.

Design/methodology/approach:
This paper is based on findings from three case companies based in Denmark. Thirty-seven semi-structured interviews were conducted with expatriates, managers and vice presidents at the three home-organisations and their subsidiaries.

Findings:
Several empirical studies, including the study presented in this paper, indicate that ethnocentrism in the home-company is a main constraint for cross-cultural learning mediated by the expatriates. It is suggested that the HR department in the home-company should create specialized professional training programs and recruit employees with practical knowledge about expatriation. However, personal and relational mentoring should be conducted by experienced and motivated individuals who are supported and recognized, but not controlled, by the HR department.

Research limitations/implications:
This research is focused on Danish companies and further research is needed to test the theories in other cultural settings.

Practical implications:
This research can help companies and expatriates gain a more successful expatriation period.

Originality/value:
The value and role of mentorship is detailed from a theoretical and practical perspective, which adds to the body of literature on expatriates and mentorship.
Mest trafiksikkerhed for pengene
Ny forskning fra DTU peger på, at det er muligt at forbedre prioriteringen af infrastrukturforbedringer på baggrund af viden om vejenes tilstand, de skønnede udbedringsomkostninger samt uheldsforekomst og alvorlighedsgrad.

Methods of 3D data applications to inform design decisions for physical comfort

Many everyday tasks require physical contact with products, such as helmets, headsets, etc. There is a drive for comfortable products that fit the task and the human body, especially in the industry of external ear worn products. Past research on anthropometry stresses that positive comfort is enhanced when there is sufficient knowledge of human factors. The majority of these studies focus only on the acquirement and presentation of anthropometric data. This paper examines the incorporation of anthropometry in the design of external-ear devices. The aim of this paper is to provide different methods to support design applications (ways of analysis) of 3-dimensional head and ear data with a focus on external ear products. 200 persons representing the Danish population were scanned. The 3-d data was collected, refined and analysed. A matrix containing 29 new ear dimensions was generated. An analysis of the dataset through understanding of human and product geometry and methods of visualisation of the dataset generated an additional number of 9 advanced dimensions. The paper finally presents all phases of the analysis of the 3D data in the form of a methodological framework. The paper contributes with, in addition to the methodological framework, techniques to extract data based on a mathematical and product understanding, visualisation of data and manual extractions and how the data can be used to define archetypes for focus groups and other qualitative assessments. In their endeavour to develop successful and comfortable products designers should focus more on fitting the task into the human by benchmarking human dimensions against product data.

Modeling Group Perceptions Using Stochastic Simulation: Scaling Issues in the Multiplicative AHP

This paper proposes a new decision support approach for applying stochastic simulation to the multiplicative analytic hierarchy process (AHP) in order to deal with issues concerning the scale parameter. The paper suggests a new approach that captures the influence from the scale parameter by making use of probability distributions. Herein, the uncertainty both with regard to the scale and the inherent randomness from the parameter is captured by probabilistic input and output distributions. Provided that each alternative and criteria under consideration are independent it is assumed that the embedded uncertainty from the progression factors remains the same. The result is then an interval estimate for each alternative's final scores. This can lead to overlapping intervals of scores which may be interpreted as possible rank reversals. Thus, the decision support approach makes it possible to calculate the probability of overlapping for any given set of pairwise comparisons.

Modeling of electricity savings in the Danish household sector using Balmorel

In this paper we examine the investments in energy-efficient household appliances from an energy system perspective. We consider a set of ten appliances constituting the majority of the electricity consumption in the private household sector, and investigate whether investing in improved energy efficiency can compete with the cost of electricity supply from existing or new power plants. To assess the analysis, Balmorel, a linear optimization model for heat and power sectors, has been extended in order to assess the best possible investments in more efficient household appliances. The model is non-exclusively tested on the Danish energy system under different scenarios, and computational experiments show that several energy efficiency measures in the household sector should be regarded as valuable investments, while others would require some form of support to become profitable. The analysis also reveals the impact that changes in the Danish electricity consumption would have on the surrounding countries in terms of power system configuration and emission reduction.

Modelling production system architectures in the early phases of product development

This article suggests a framework for modelling a production system architecture in the early phases of product development. The challenge in these phases is that the products to be produced are not completely defined and yet decisions need to be made early in the process on what investments are needed and appropriate to enable determination of obtainable product quality. In order to meet this challenge, it is suggested that a visual modelling framework be adopted that clarifies which product and production features are known at a specific time of the project and which features will be worked on – leading to an improved basis for prioritizing activities in the project. Requirements for the contents of the framework are presented, and literature on production and system models is reviewed. The production system architecture modelling framework is founded on methods and approaches in literature and adjusted to fit the modelling requirements of a production system architecture at an early phase of development. The production system architecture models capture and describe the structure, capabilities and expansions of the production system architecture.
underdevelopment. The production system architecture modelling framework is tested in a case study, and the results indicate that the modelling process facilitates identification of critical factors of the production system architecture, that the production system architecture models capture and describe the structure, capabilities and expansions of a production system architecture under development, and that the production system architecture models can facilitate dialogue on the production system architecture between heterogeneous stakeholder groups.

Modelling the relation between income and commuting distance

We discuss the distribution of commuting distances and its relation to income. Using data from Denmark, the UK and the USA, we show that the commuting distance is (i) broadly distributed with a slow decaying tail that can be fitted by a power law with exponent $\gamma \approx 3$ and (ii) an average growing slowly as a power law with an exponent less than one that depends on the country considered. The classical theory for job search is based on the idea that workers evaluate the wage of potential jobs as they arrive sequentially through time, and extending this model with space, we obtain predictions that are strongly contradicted by our empirical findings. We propose an alternative model that is based on the idea that workers evaluate potential jobs based on a quality aspect and that workers search for jobs sequentially across space. We also assume that the density of potential jobs depends on the skills of the worker and decreases with the wage. The predicted distribution of commuting distances decays as $1/r^3$ and is independent of the distribution of the quality of jobs. We find our alternative model to be in agreement with our data. This type of approach opens new perspectives for the modelling of mobility.

Modelling the socio-economic impacts of modern bioenergy in rural communities in Ghana

This study analyses ex-ante socio-economic impacts of biogas systems using a remote rural community in Ghana as a case study. An analysis was performed for a 300 m3 bio-digester that relies on crop residue and animal manure as feedstock to produce methane gas for cooking using selected bioenergy economic and social indicators. With a 10% discount rate, a 30 year bio-digester lifetime and methane tariff starting at US$ 0.7/m3, the project will have a Net Present Value of approximately US$ 22,000, 16 year payback and an Internal Rate of Return of 11%. The project will create 4 full time unskilled labour positions during the investment year and 3 positions during operation years. Using methane from the bio-digester for cooking will displace approximately 170 tonnes of firewood per year and save the women in the community a total of 3400 hours per year not fetching firewood. However, only 5% of households are willing to pay the base tariff of US$ 30/m3 with up to 60% willing to pay less than half the monthly tariff. To make tariffs affordable to rural households, there is the need for subsidy schemes from government or relevant agencies. © 2016 Elsevier Ltd. All rights reserved.

Multi-pathway exposure modelling of chemicals in cosmetics with application to shampoo
We present a novel multi-pathway, mass balance based, fate and exposure model compatible with life cycle and high-throughput screening assessments of chemicals in cosmetic products. The exposures through product use as well as post-use emissions and environmental media were quantified based on the chemical mass originally applied via a product, multiplied by the product intake fractions (PiF, the fraction of a chemical in a product that is taken in by exposed persons) to yield intake rates. The average PiFs for the evaluated chemicals in shampoo ranged from 3 × 10− 4 up to 0.3 for rapidly absorbed ingredients. Average intake rates ranged between nano- and micrograms per kilogram bodyweight per day; the order of chemical prioritization was strongly affected by the ingredient concentration in shampoo. Dermal intake and inhalation (for 20% of the evaluated chemicals) during use dominated exposure, while the skin permeation coefficient dominated the estimated uncertainties. The fraction of chemical taken in by a shampoo user often exceeded, by orders of magnitude, the aggregated fraction taken in by the population through post-use environmental emissions. Chemicals with relatively high octanol-water partitioning and/or volatility, and low molecular weight tended to have higher use stage exposure. Chemicals with low intakes during use (< 1%) and subsequent high post-use emissions, however, may yield comparable intake for a member of the general population. The presented PiF based framework offers a novel and critical advancement for life cycle assessments and high-throughput exposure screening of chemicals in cosmetic products demonstrating the importance of consistent consideration of near- and far-field multi-pathway exposures.

Natural fibre selection for composite eco-design

Natural fibre composites (NFC) are gaining interest in manufacturing because they address some of the environmental problems of traditional composites: use of non-renewable resources, and large impacts related to their production and disposal. Since natural fibres are not yet optimized for composite production, it is crucial to identify the most appropriate applications, and determine the optimal fibre/matrix ratio. A methodology is proposed for early-stage decisions support on selection of bio-composite materials. Results help identify the application with the largest reduction in environmental burden and show that the fibre/matrix combination with the lowest environmental burden also has the best mechanical properties.
Natural resources as an area of protection in LCA - outcomes of the discussion by the working group on resources within the UNEP-SETAC Life Cycle Initiative

The topic of resources as an area of protection (AoP) in life cycle assessment (LCA) is being discussed within an expert group under the umbrella of the Life Cycle Initiative by the United Nations Environment Programme (UNEP) and the Society for Environmental Toxicology and Chemistry (SETAC). The AoP ‘Natural Resources’ is neither well defined nor agreed upon. Furthermore, there is currently no life cycle impact assessment (LCIA) method available that is able to consistently assess impacts at midpoint and endpoint level across different resource categories (minerals/metals and fossil fuels, water, land/soil, biotic resources like wild plants and animals). Definitions and categorizations of natural resources differ and there is no agreement on what methods should be considered midpoint or endpoint methods because there is no agreement (at midpoint and endpoint) on what impact should be assessed (is it reduced availability, is it depletion, is it increased energy use or costs due to future resource extraction, etc.?). The merit of this working group is the broad analysis of available methods considering different resources and their integrated discussion according to the methods’ underlying principles (e.g. use-to-availability ratios, backup technology approaches, etc.). This is the basis on which recommendations for best practice with existing methods and indications for further research and development will be given. At the time of the SETAC 2016 conference, the group should have these recommendations ready.

Nearshore versus Offshore: Comparative Cost and Competitive Advantages
Currently there exist high expectations for the development of wind energy, particularly in Europe, out of which offshore wind turbine developments will be central as tools to achieve current energy targets. The choice between nearshore and (far)-offshore is particularly relevant, both because of increased public resistance due to visual disamenities produced by nearshore projects, and because of the potential cost reduction benefits attained by building wind farms closer to the shore.

Nearshore Versus Offshore: Comparative Cost and Competitive Advantages
Currently there exist high expectations for the development of wind energy, particularly in Europe, out of which offshore wind turbine developments will be central as tools to achieve current energy targets. The choice between nearshore and (far)-offshore is particularly relevant, both because of increased public resistance due to visual disamenities produced by nearshore projects, and because of the potential cost reduction benefits attained by building wind farms closer to the shore.
Near-shore wind turbines: Does their cost advantage outweigh the preferences for visual disamenities reduction they elicit?

It is widely accepted that engaging with end-users to elicit their needs is beneficial when designing a new artefact. This can be particularly challenging, however, when end-users are limited in their ability to provide input. When there is broad variation in users' needs, a further challenge is to include the large number of users required to represent the entire population. Failure to do so may lead to a solution that is over specialised to fit the needs of only a small subset of users. Both challenges are common in healthcare applications in which the end-user is also care recipient (or patient). What if instead of trying to engage vastly many users in design activities, we could hear the voice of the patient by tapping into existing channels within the health care service system? Many interactions between healthcare providers and patients involve knowledge transfer. Observing these could inform designers about patients' support needs and healthcare providers' information needs. Healthcare professionals offer a wealth of knowledge based on a clinical understanding of the condition as well as experience listening to patients' problems. Especially where patients are in denial about their condition, their healthcare providers might offer more detailed information than the patient themselves regarding their needs. Since each patient knows only their own experience, whereas healthcare professionals encounter numerous patients, their perspective is more robust against inter-patient variation, and they are able to comment on trends, scale or proportions. We therefore explore how users' needs can be elicited by observing activities in which information is already being shared and discussed in the care process, and from the extensive knowledge of healthcare professionals. This is particularly relevant for pervasive healthcare technology, in which established methods for engaging users to elicit their needs can be difficult or even impossible to apply. In this paper we document our needs elicitation process in a relevant example as a method story, and present our findings and reflections on this as the key contribution of this work.

Network Insights for Partner Selection in Inter-Organisational New Product Development Projects

Selecting partners for new product development (NPD) is an important yet under-supported task. This paper focuses on decision-making support for the NPD collaboration stages of partner exploration and search. We provide a conceptual framework for a network-based platform to identify potential research and innovation partners. The framework integrates prior research on factors determining successful NPD collaborations and makes the factors actionable by connecting them to what is often publicly available data. Four categories of success factors for collaborations are included in the framework: technological closeness, relational closeness, geographical closeness, and a set of organisational variables. In order to identify a subset of new product development partners and aid the selection process, three characteristics of NPD projects are considered as mediators of those success factors: the desired degree of innovativeness of the NPD project, the initial technological maturity of the NPD project, and the combination of time and budget constraints. The proposed framework describes each of these factors, their mediators, and the interplay between them. Using the conceptual framework as a guide, we also propose and illustrate with examples the network-based platform to explore NPD partners. The developed framework and platform are part of Net-Sights, an ongoing research project to develop open-source decision-support tools for network insights. The first version of this tool will soon be available as an online platform to support inter-organisational and collaborative sustainable production projects in Denmark.

Non-disruptive regime changes-The case of competing energy efficient lighting trajectories

Technologies within the same industry are expected to follow similar patterns of innovation, and when the dominant patterns change, this is often expected to have disruptive effects on the industry. However, the three most recent lighting technologies (fluorescent, compact fluorescent, and LED) show different patterns of innovative activities despite similarities in the determinants of innovation; and we observed multiple technological regimes within the lighting industry. Furthermore, we observed changes in these innovative patterns without widespread disruptive effects. While FL and LED quickly improved once they were introduced, CFL struggled for decades. We present an historical case study of the emergence and development of the different regimes and we present possible explanations to be found in market structure and selection criteria. The analysis shows the important role for policymakers in stimulating new technologies in industries with undesirable Mark II pattern through the influence of all the dimensions of the technological regimes.

A common interest in developing a reliable, sustainable and affordable energy system was the main driver for the Nordic energy policy cooperation since the creation of the Nordic Council of Ministers. The diversity of the energy systems in the Nordic countries facilitated this cooperation, not least in the power sector. Over the years, five focus areas have been addressed. Energy security of supply triggered the Nordic cooperation with the need to develop a long-term energy policy. This required decision-making support and energy systems analyses based on reliable and valid data, modelling and policy scenarios.

Energy markets developed from a political wish to make the important oil and gas sector an area of cooperation that led finally to the recognition that there was no common ground for closer cooperation in this field. However, power utilities and grid companies cooperated across the borders long before the politicians supported and pushed for further cooperation. Energy efficiency was addressed by a portfolio of activities ranging from knowledge-sharing, public campaigns, labelling and standardisation of products. The need to address environmental degradation was inspired by the UN Brundtland Commission Report, and climate change became a common concern. Energy technology cooperation was an integral part of Nordic energy policy cooperation from the very beginning. The Nordic Energy Research Programme was established with funding from each of the Nordic countries, and was earmarked for Nordic projects of common interests. This created the necessary critical knowledge base in new energy technologies, energy systems and energy markets.

Nordic energy policy cooperation followed the ordinary Nordic governance structures, rules and mode of operation with Council of Ministers, supported by a committee of senior officials and a secretariat. This was characterised by an incremental development of the cooperation based on consensus, mutual understanding and trust facilitated through exchange of experiences, work groups, seminars, educational activities and mobility schemes for energy policy officials.

With the consolidation of Nordic Energy Research in 1999, the cooperation benefitted from having an institution that exclusively could focus on Nordic energy policy issues and deliver research-based decision support to decision makers in the Nordic energy sector.

Nordic organizational style and how it may support design for sustainability implementation

Design for sustainability (DfS) implementation in companies has been discussed and studied in academic literature from different perspectives, both technical and human related aspects included. The latter focus in literature has stressed upon the need for focus on the organizational characteristics, functioning style, communication patterns etc. as important determinants in DfS implementation in companies. It is in this context that this research work tends to explore if regional characteristics, that can be observed in companies, contribute/impact to the successful implementation of DfS in companies. As a case of reference, the Nordic their organizational style and its aptness presented in literature is studied and presented.

The Nordic industries have been one of the first movers on sustainability-related topics. This research work aims at exploring the Nordic style in organisations in a DfS context and is based on findings from existing literature and industrial reports in a broader field of research pertaining to the Nordics. The work investigates and presents factors and drivers that distinguish the Nordic countries from the rest of the world. A preliminary framework is also presented as part of the work to highlight how some of the most discussed DfS implementation challenges may be mitigated by the Nordic organizational style. Such an understanding may in turn inform a discussion on the potential need for customised tools, methods and approaches for implementing DfS within Nordic industry and beyond.

Obligatorisk hjelmbrug giver færre alvorlige hovedskader
I Seattle (USA) har man indført lovpligtig brug af cykelhjelm for cyklister i alle aldersgrupper. En evaluering viser, at lovpligtig hjelmbrug har en positiv effekt på alvorlighedsgraden af hovedskader og dødsfald blandt tilskadekomne cyklister. Den lovpligtige hjelmbrug medførte dog ikke et generelt fald i tilskadekomst blandt cyklister. Forskerne mener dog, at dette kan forklares med en stigning i omfanget af cykling samt en generel stigning i tilskadekomst blandt cyklister.

Off-Site Prefabrication: What Does it Require from the Trade Contractor?
The purpose of the paper is to show what is required to industrialize a building process from the standpoint of the trade contractor. Rationalization of building processes has, over the years, caught the attention of numerous IGLC papers. Although significant contributions have been made to further understand and improve existing construction processes, relatively few contributions have focused on the opportunities for industrialization from the trade contractor's perspective. This paper uses an in-depth case study to address the deployment strategy for off-site fabrication techniques and processes used for modular plumbing fixture carriers deployed on two large-scale hospital projects in the United States. Findings include the organizational and technological arrangement for prefabrication. The paper applies value stream mapping to visualize the process and improve it. Because this work looks at only one case study, the conclusions are limited in generalizability to other prefabrication operations. However, it represents an important in-depth case from the trade contractors’ perspective and will contribute to the growing body of research focused on industrialization and prefabrication in lean construction.

Online Anomaly Energy Consumption Detection Using Lambda Architecture
With the widely use of smart meters in the energy sector, anomaly detection becomes a crucial mean to study the unusual consumption behaviors of customers, and to discover unexpected events of using energy promptly. Detecting consumption anomalies is, essentially, a real-time big data analytics problem, which does data mining on a large amount of parallel data streams from smart meters. In this paper, we propose a supervised learning and statistical-based anomaly detection method, and implement a Lambda system using the in-memory distributed computing framework, Spark and its extension Spark Streaming. The system supports not only iterative refreshing the detection models from scalable data sets, but also real-time anomaly detection on scalable live data streams. This paper empirically evaluates the system and
the detection algorithm, and the results show the effectiveness and the scalability of the lambda detection system.

On the need for integrating LCA into decision making
The need for sustainable solutions has gained attention both in academia and industry research due to increasing demands of human beings, which are incompatible with limitations in resources availability. Several methods, such as Life Cycle Assessment (LCA), were developed in the past decades to assess the environmental profile of products and services. However, when decision makers have several alternatives at hand to solve a problem, environmental performance is not the only criterion for choosing the best alternative. Other criteria such as risks and economical costs and benefits that are associated with the alternatives will also influence the final choice. Sometimes the most environmentally sustainable alternative may not be the safest or cheapest one. How to make a balanced decision considering environmental performance together with other criteria is not straightforward.

Decision analysis is broadly used to help decision makers identify the best solution among alternatives. The decision is based on expected utility generation, which incorporates consequences (or impacts) associated with each alternative. Depending on the research field and goal of the study, the included consequences can be e.g. environmental impacts, property damages from natural hazards and/or human health impacts. We examined the current decision analysis practice as it is applied in different research fields. The review shows that generally environmental impacts are considered less often than the other consequences. Meanwhile, LCA has been applied in many research fields to assess a wide range of environmental impacts associated with products or services. There is a huge potential for integrating LCA into other decision analysis tools to include assessments of the environmental profile of alternatives. This will provide the possibility of systematical inclusion of environmental considerations in the decision making process, thus facilitating a more holistic decision. However, due to different scopes and purposes of LCA and other decision analysis tools, the integration is not straightforward. The lack of consistency in e.g. system boundaries and handling of uncertainty needs to be carefully managed.

Operational impact of product variety in the process industry

The purpose of this research article is to examine the impact of product variety on production performance in the process industry. As the number of product variants sold by a process company typically impacts the run length, production data from a mineral wool insulation manufacturer is analyzed to quantify the impact of longer runs on productivity. In testing the hypothesis that longer runs lead to higher productivity, the results show that the number of variants in itself is not a sufficient parameter to explain the variation in production performance; rather, the different types of product variants and their production sequence must also be considered. Based on the findings, a method for quantifying the production cost of product variety in the process industry is developed, adding to the literature a rich case howcasing factors which influence production performance and the impact is measured with metrics.

Operational implications of accepting and denying whether a true value of risk exists

It is suggested to look on probabilistic risk quantities and concepts through the prism of accepting one of the views: whether a true value of risk exists or not. It will be argued that discussions until now have been primarily focused on closely related topics that are different from the suggested one.
In general, the values of risks are not known precisely and the analyst has the option to consider that convergence to a precise value of risk is possible in the limit. That is, the true value exists but due to limited time, resources or other limitations in assessing probabilities it is not known at the time being. Following this prospective, a single probability distribution over a set of possible outcomes can be chosen that is tacitly regarded as a ‘true’ or ‘ideal’ model of uncertainty. After that, computing other probabilistic risk measures of interest becomes a rather easy mathematical exercise. In fact, accepting the true-value view does not make the adherent use only a single probability distribution as a model of uncertainty. One can introduce a class of distributions in which a particular member is considered a plausible candidate to be an ideal distribution. Then, a risk quantity of interest can be computed for each distribution-candidate and after that, lower and upper bounds can be constructed as assessments of risk. This is a robust way of compensating for ignorance that studies the sensitivity of derived numerical values to variations in probability distributions.

Operation and maintenance service provision in uncertain times – the case of the FL Smidth Group during the Arab Spring

This case was written by Melanie E. Kreye. It was compiled based on primary data collection by the author such as interviews and observations and published secondary data by the case companies. The case was made possible through the generous co-operation of the FLSmidth Group. It is intended to be used as a basis for class discussion.

Optimal retirement planning with a focus on single and joint life annuities
We optimize the asset allocation, consumption and bequest decisions of a couple with an uncertain lifetime. The asset menu consists of zero coupon bonds and pure endowments with different maturities, whole life annuities and stocks. The pure endowments pay either fixed or variable benefits, and, similarly to the whole life annuities, are contingent on either a single or a joint lifetime. We model the stock returns and the parameters for the term structure with a vector autoregressive model, thus considering time-varying investment opportunities. To find the optimal solution we use a multi-stage stochastic programming approach, which allows for including complex surrender charges on pure endowments and annuities, as well as transaction costs on stocks and bonds. Our findings indicate that despite high surrender charges, households should invest in a wide combination of life contingent products with different maturities and underlying financial risk.

Optimal trade-offs between energy efficiency improvements and additional renewable energy supply: A review of international experiences

Energy is a commodity used worldwide, representing a vital input for social and economic development. Due to continuous growth, energy demand has increased. Solutions have been proposed in order to satisfy the increase in demand, often implying the increase of capacity of the power mix. Meanwhile, current issues concerning climate change and fossil fuels depletion has moved attention towards cleaner ways to produce energy. This trend facilitated the breakthrough of renewable technologies. Since then, support policies have promoted the large deployment of renewables, without considering enough the improvements made in the energy saving field. Indeed, little attention has been paid to implement energy efficiency measures, which has resulted in scenarios where expedients for a wise use of energy (e.g. energy savings and renewables share) are unbalanced. The aim of this paper is to review and evaluate international experiences on finding the optimal trade-off between efficiency improvements and additional renewable energy supply. A critical review of each technique, focusing on purposes, methodology and outcomes, is provided along with a review of tools adopted for the analyses. The models are categorized and presented according to their main characteristics (e.g. bottom-up/top-down model, regional/national analysis, partial/general equilibrium, static/dynamic model). The results of this paper provide, to the decision-makers, informations useful to identify a suitable analysis for investigate on the optimal trade-off between renewables and energy efficiency measures in energy-systems under different objectives.

Optimal Turbine Allocation for Offshore and Onshore Wind Farms

Green energy became a topic of great interest in the recent years, as every year the demand for energy is increasing and the old resources, fossil fuels in particular, are pollutant and are becoming scarce. As a result, many countries have ambitious plans regarding green energy production. In particular, lots of money and energy are spent on the optimal design of wind farms, as an efficient use of the available resources is instrumental for their economical success. In the present paper we address the optimization of turbine positions, which is one of the most relevant problems in the design of a wind farm, and propose a heuristic approach based on Mixed-Integer Linear Programming techniques. Computational results on very large scale instances prove the practical viability of the approach.
Optimised biogas production from the co-digestion of sugar beet with pig slurry: Integrating energy, GHG and economic accounting

Several countries have established a number of increased targets for energy production from renewable sources. Biogas production, which will play a key role in future energy systems largely based on renewable sources, is expected to grow significantly in the next few decades. To achieve these ambitious targets, the biogas production chain has to be optimised to obtain economic viability and environmental sustainability while making use of a diversified range of feedstock materials, including agricultural residues, agro-industrial residues and, to some extent, dedicated energy crops. In this study, we integrated energetic, GHG and economic analysis to optimise biogas production from the co-digestion of pig slurry (PS) and sugar beet pulp silage (SB). We found that utilising SB as a co-substrate improves the energy and GHG balances, mostly because of increased energy production. However, utilising SB negatively affects the profitability of biogas production, because of the increased costs involved in feedstock supply. The scale of the processing plant is neutral in terms of profitability when SB is added. The results indicate that medium-to large-sized biogas plants, using low shares of SB co-substrate, may be the preferred solution.
Optimization of preventive condition-based tamping for railway tracks

This work considers the scheduling of railway preventive condition-based tamping, which is the maintenance operation performed to restore the track irregularities to ensure both safety and comfort for passengers and freight. The problem is to determine when to perform the tamping on which section for given railway tracks over a planning horizon. The objective is to minimize the Net Present Costs (NPC) considering the following technical and economic factors: 1) track quality (the standard deviation of the longitudinal level) degradation over time; 2) track quality thresholds based on train speed limits; 3) the impact of previous tamping operations on the track quality recovery; 4) track geometrical alignment; 5) tamping machine operation factors and finally 6) the discount rate. In this work, a Mixed Integer Linear Programming (MILP) model
is formulated and tested on data from the railway corridor between Odense and Fredericia, part of the busiest main line in Denmark. Computational experiments are carried out to compare our model to the existing models in the literature. The results show that taking into consideration these previously overlooked technical and economic factors 3, 5 and 6 can prevent under-estimation of required tamping operations, produce a more economic solution, prevent unnecessary early tamping, and improve the track quality by 2 percent.

Optimization of the drayage problem using exact methods

Major liner shipping companies offer pre- and end-haulage as part of a door-to-door service, but unfortunately pre- and end-haulage is frequently one of the major bottlenecks in efficient liner shipping due to the lack of coordination between customers. In this paper, we apply techniques from vehicle routing problems to schedule pre- and end-haulage of containers, and perform tests on data from a major liner shipping company. The paper considers several versions of the scheduling problem such as having multiple empty container depots, and having to balance the empty container depot levels. The influence of the side constraints on the overall cost is analysed. By exploring the fact that the number of possible routes in the considered case is quite limited, we show that the model can be solved within a minute by use of column enumeration. Alternative constraints and problem formulations, such as balancing empty container storage level at depots, are considered. Computational results are reported on real-life data from a major liner shipping company.

Optimizing ETL by a Two-level Data Staging Method

In data warehousing, the data from source systems are populated into a central data warehouse (DW) through extraction, transformation and loading (ETL). The standard ETL approach usually uses sequential jobs to process the data with dependencies, such as dimension and fact data. It is a non-trivial task to process the so-called early-/late-arriving data, which arrive out of order. This paper proposes a two-level data staging area method to optimize ETL. The proposed method is an all-in-one solution that supports processing different types of data from operational systems, including early-/late-arriving data, and fast-/slowly-changing data. The introduced additional staging area decouples loading process from data extraction and transformation, which improves ETL flexibility and minimizes intervention to the data warehouse. This paper evaluates the proposed method empirically, which shows that it is more efficient and less intrusive than the standard ETL method.

Optimizing inventory management in the insulation manufacturing industry

Inventory issues within the insulation manufacturing industry are essential for competitiveness. However, they are largely unexplored in academic literature. Therefore the aim of this paper is to address the research question: “What approach to inventory management provides the best balance between service level and cost for the insulation manufacturing industry?” This is done through an in-depth case study of a world-leading company within this industry, with focus on two of its factories. This paper contributes with empirical research within operations management in a sector which has not been well-researched and presents results which are useful for both practitioners and academics.

Optimizing wind farm cable routing considering power losses

Wind energy is the fastest growing source of renewable energy, but as wind farms are getting larger and more remotely located, installation and infrastructure costs are rising. It is estimated that the expenses for electrical infrastructure account for 15-30% of the overall initial costs, hence it is important to optimize o shore inter-array cable routing. The routing should connect all turbines to one (or more) o shore sub-station(s) while respecting cable capacities, no-cross restrictions, connection-limits at the substation, and obstacles at the site. The objective is to minimize both the capital that must be spent immediately in cable and installation costs, and the future reduced revenues due to power losses. The latter goal
has not been addressed in previous work. We present a Mixed-Integer Linear Programming approach to optimize the routing using both exact and math-heuristic methods. In the power losses computation, wind scenarios are handled efficiently as part of the preprocessing, resulting in a MIP model of only slightly larger size. A library of real-life instances is introduced and made publicly available for benchmarking. Computational results on this testbed show the viability of our methods, proving that savings in the order of millions of Euro can be achieved.

Organisation Design for Servitized Manufacturers

Organising Sustainable Transition: Understanding the Product, Project and Service Domain of the Built Environment

Sustainable transition of the built environment construction industry is challenging the existing construction practices and business models. This article presents a framework for understanding and facilitating sustainable transition in the built environment. The framework was developed through a four years innovation project based on theories on sectorial and business model innovation and ten detailed case studies of different types of companies and their experimentation with different management and sustainability concepts. The framework interprets the construction industry as a collection of three generic domains - the Project, Product and Service domain - with widely different markets, companies, business models and regulation. Besides identifying the characteristics of the different domains, the findings show that these domains are interdependent, but largely live their own lives with internal agendas. Furthermore, it is shown that the domains are subject to more or less consciously coordinated innovation activities. The research concludes that the three-domain-model represents a promising framework for understanding and facilitating sustainable transition of the construction industry and built environment.
**Orientations and outcome of interdisciplinary research: the case of research behaviour in translational medical science**

The importance of interdisciplinary research in accelerating the progress and commercialization of science is widely recognized, yet little is known about how academic research self-organizes towards interdisciplinarity. In this paper, we therefore explore the micro-level behavior of researchers as they venture into a promising space for interdisciplinary research, namely translational research—a bridge between basic and applied biomedical research. More specifically, we ask (1) whether the researchers who choose to engage in translational research have a strong scientific record, (2) how interdisciplinary research spanning basic and applied research influences the output of academic research, and (3) how different disciplinary distance in interdisciplinary research contributes to reputational benefits of researchers. We find that for some types of collaboration, interdisciplinarity results in more highly cited research, while in others it is not, and look for explanations for this difference. Our results show that translational research draws higher citations when it involves university researchers from the most basic end of the disciplinary spectrum, and when its issues are directed at basic (rather than applied) research.

Overplanting in offshore wind power plants in different regulatory regimes

Offshore wind power’s journey towards being competitive with other generation technologies relies on technical innovation and maturation, but also on further optimisation of proven and mature solutions. Capacity optimisation or so-called overplanting is one example of optimisation, which is performed by installing a larger wind power capacity than stipulated in the connection agreement with transmission system operators (TSOs). By developing a discounted cash flow (DCF) model, the paper investigates how both regulatory regimes and geographic characteristics of dedicated offshore wind development areas affect the viability of overplanting. The analysis comprises hypothetical scenarios of the distinctive offshore wind markets of the United Kingdom and Denmark and thereby elucidates the key aspects influencing the value of overplanting. This work’s findings show that the UK regulatory framework results more favourable to overplanting. The results indicate that current conceivable offshore wind power plants in the UK can increase their economic value by around 30 mio AC when optimising their capacity setup. In Denmark, current regulations are not suitable for overplanting causing loss of value when optimising the capacity design of wind power plants.

Participatory methods for initiating manufacturing employees’ involvement in product innovation

Employee-driven innovation has the potential to improve product innovation by involving employees as innovative resources. However, it can be a challenge to turn the potential into a reality of collaboration practices across organizational structures and culture. Through an interactive research approach that we apply to two case companies, this paper presents an empirical study of how to initiate involvement of manufacturing employees in R&D activities. We have used participatory methods from design thinking that has the ability to create relations between employees from different backgrounds and through a series of facilitated workshops we have investigated how these methods can initiate employee involvement. We see that participatory methods can improve understanding and relation between R&D and manufacturing departments, and thereby support a creative collaboration and emergence of employee-driven innovation practices.

Passenger Perspectives in Railway Timetabling: A Literature Review

When looking at railway planning, a discrepancy exists between planners who focus on the train operations and publish fixed railway schedules, and passengers who look not only at the schedules but also at the entirety of their trip, from access to waiting to on-board travel and egress. Looking into this discrepancy is essential, as assessing railway performances by merely measuring train punctuality would provide an unfair picture of the level of service experienced by passengers. Firstly, passengers’ delays are often significantly larger than the train delays responsible for the passengers to be late. Secondly, trains’ punctuality is often strictly related to too tight schedules that in turn might translate into knock-on delays for longer dwelling times at stations, trip delays for increased risk of missing transfer connections, and uncertain assessment of the level of service experienced, especially with fluctuating passenger demand. A key aspect is the robustness of railway timetables. Empirical evidence indicates that passengers give more importance to travel time certainty than travel time reductions, as passengers associate an inherent disutility with travel time uncertainty. This disutility may be broadly interpreted as an anxiety cost for the need for having contingency plans in case of disruptions, and may be looked at as the motivator for the need for delay-robust railway timetables. Interestingly, passenger-oriented optimisation studies considering robustness in railway planning typically limit their emphasis on passengers to the consideration of transfer maintenance. Clearly, passengers’ travel behaviour is far more complex and multi-faceted and thus several other aspects should be considered, as becoming more and more evident from passenger surveys. The current literature review starts by looking at the parameters that railway optimisation/planning studies are focused on and the key performance indicators that impact railway planning. The attention then turns to the parameters influencing passengers’ perceptions and travel experiences. Finally, the review proposes guidelines on how to reduce the gap between the operators’ railway planning and performance measurement on the one hand and the passengers’ perception of the railway performance on the other hand. Thereby, the conclusions create a foundation for a more passenger-oriented railway timetabling ensuring that passengers are provided with the best service possible with the resources available.
As of January 2015, the new maximum limit of fuel sulfur content for ships sailing within emission control areas has been reduced to 0.1%. A critical decision for ship owners in advance of the new limits was the selection of an abatement method that complies with the regulations. Two main options exist: investing in scrubber systems that remove sulfur dioxide emissions from the exhaust and switching to low-sulfur fuel when sailing in regulated waters. The first option would involve significant capital costs, while the latter would lead to operating cost increases because of the higher price of the fuel used. This paper presents a literature review of emissions abatement options and relevant research in the field. A cost–benefit methodology to assess emission reduction investments from ship owners is also presented. A study examined the effects of recent drops in bunker fuel price to the payback period of a potential scrubber investment. The results show that lower prices would significantly delay the payback period of such investments, up to two times in some cases. The case studies present the emissions generation through each option for representative short sea shipping routes. The repercussions of low-sulfur policies on large emission reduction investments including cold ironing are examined, along with implications of slow steaming for their respective payback periods. Recommendations are made for research in anticipation of future regulations and technological improvements.

Personal Metabolism (PM) coupled with Life Cycle Assessment (LCA) model: Danish Case Study
Sustainable and informed resource consumption is the key to make everyday living sustainable for entire populations. An intelligent and strategic way of addressing the challenges related with sustainable development of the everyday living of consumers is to identify consumption-determined hotspots in terms of environmental and health burdens, as well as resource consumptions. Analyzing consumer life styles in terms of consumption patterns in order to identify hotspots is hence the focus of this study. This is achieved by taking into account the entire value chain of the commodities consumed in the context of environmental and human health burdens, as well as resource consumptions. A systematic commodity consumption, commodity disposal, and life style survey of 1281 persons living in urbanized Danish areas was conducted. The findings of the survey showed new impact dimensions in terms of Personal Metabolism (PM) patterns of residents living in urbanized areas of Denmark. Extending the PM analysis with Life Cycle Assessment (LCA) provided a clear picture of the per capita environmental and human health burdens, as well as resource consumptions, and the exact origin hereof. A generic PM-LCA Model for all the 1281 persons was set-up in Gabi 6. The assessment results obtained applying the model on all 1281 personal consumption scenarios yielded the 1281 Personal Impact Profiles (PIPs). Consumption of food and energy (electricity and thermal energy) proved to be the primary impact sources of PM, followed by transport. The PIPs further revealed that behavioral factors (e.g. different diets, use of cars, household size) affect the profiles. Hence, behavioral changes are one means out of many that humanity will most likely have to rely on during the sustainable development process. The results of this study will help the Danish and other comparable populations to identify and prioritize the steps towards reducing their environmental, human health, and resource consumption burdens.

**Pervasive assistive technology for people with dementia: a UCD case**

Smart mobile and wearable technology offers exciting opportunities to support people with dementia (PwD). Its ubiquity and popularity could even benefit user adoption—a great challenge for assistive technology (AT) for PwD that calls for user-centred design (UCD) methods. This study describes a user-centred approach to developing and testing AT based on off-the-shelf pervasive technologies. A prototype is created by combining a smartphone, smartwatch, and various applications to offer six support features. This is tested among five end-users (PwD) and their caregivers. Controlled usability testing was followed by field testing in a real-world context. Data is gathered from video recordings, interaction logs, system usability scale questionnaires, logbooks, application usage logs, and interviews structured on the unified theory of acceptance and use of technology model. The data is analysed to evaluate usability, usefulness, and user acceptance. Results show some promise for user adoption, but highlight challenges to be overcome, emphasising personalisation and familiarity as key considerations. The complete findings regarding usability issues, usefulness of support features and four identified adoption profiles are used to provide a set of recommendations for practitioners and further research. These contribute toward UCD practices for improved smart, pervasive AT for dementia.

**Planning of Midwives**

At a hospital in Denmark around 40 midwives support the pregnancy of approx. 6000 pregnant women every year. Their role is to monitor the pregnancies and prepare the women for labour. Based on the due date of a woman, authority guidelines prescribe specific and mostly rather narrow time windows within which the pregnant woman should have consultations with a midwife. Therefore, once a pregnant woman enters the system, here sequence of consultations for the time period until labour is fairly fixed. There is a clear goal that, as far as possible, each pregnant woman should see the same midwife at every consultation. Every week the newly arrived pregnant women are assigned an arbitrary free time slot belonging to a specific midwife. In turn this midwife is expected to have consultations with this woman in specific weeks according to the authority guidelines. This random assignment of pregnant women to specific midwives, without any concern to the midwives’ future schedules, means that each midwife has a very unbalanced workload over the year. Furthermore, it means that there is an imbalance between the workloads of the different midwives. The aim of this project is therefore to devise a method that can make a fair distribution of pregnant women among the midwives. The distribution should result in a balanced work load for each midwife and a balanced work
load among the midwives while at the same time making sure that the time windows for consultations are not violated.

**Policy analysis of electricity demand flexibility**
The large-scale development of variable renewable energy sources, like wind and solar power, increases the demand for flexibility in power systems. At the same time, their electricity production replaces that of conventional power plants – the traditional suppliers of flexibility, and consequently, a new flexible infrastructure needs to be established. This thesis addresses the policy dimension of the flexibility challenge with a focus on Denmark, a country committed politically in two ways that make it particularly interesting: first, a commitment to renewable energy formulated as a long-term vision of becoming independent of fossil fuels; and second, a commitment to liberalised energy sectors with a notably progressive approach to market-based operations. The crucial question of how it will be possible to balance the Danish electricity system with large amounts of variable renewable production, primarily wind power, is still under debate. To maintain reliability in the most cost-efficient way, a policy strategy aiming at flexibility needs to be developed. Technologically, several different options are available to fulfil the requirement. A part of the solution may be to make use of idle flexibility on the demand side. Its potential could be substantial and technical solutions are available. Still, demand flexibility is largely unutilised and establishing an enabling policy and regulatory framework has been identified as one of the major challenges. While the latest Danish energy policies include a clear commitment to develop an "intelligent" energy system that utilises the flexibility potential of the demand side, a coherent policy strategy covering all aspects of the flexibility challenge has not yet been defined. By use of economic models and concepts of policy analysis, this thesis considers several policy options aiming at demand flexibility in terms of their effectiveness to induce adoption and their efficiency in creating system value while accounting for the specific characteristics of the demand side. The thesis suggests barriers relevant to be addressed due to either market failures in the classic economic sense or systemic failures founded in market design, rules and regulations. The analysis covers impacts of failures stemming from incomplete markets for flexibility and inappropriate regulation that distort the observed value or risks of demand flexibility. Furthermore, it considers various types of transaction costs related to adopting a demand response contract (switching costs) and to activation (monitoring and decision costs). The thesis develops methods to quantify the impacts of these failures and applies them in relation to the Danish case.

Switching costs are estimated and found to be a major barrier to the adoption of dynamic pricing schemes in spite of the benefits that could be achieved. As the cost of adoption may be difficult to influence directly, policies may aim at increasing the benefits of flexible demand. One suggested option is to address the issue of incomplete markets and expand market access of flexible demand in the spatial and time dimensions. The value of improving the access of the demand side to intra-hourly reserve markets is found to be substantial. Quantitative findings of the thesis suggest that the reserve value of flexible demand may be significantly higher than the value in hourly spot markets. Another improvement might be achieved by adjusting distortional electricity price elements. It can be shown that value-based taxation, even if applied to smaller portions of the electricity taxes and levies, generates benefits sufficient to exceed switching cost estimates. Monitoring and decision costs can be caused by the complexity of pricing schemes and hamper efficient response. Even though real-time pricing generates the highest benefits in theory, results of the thesis suggest that simplified schemes with minimal monitoring and decision costs would generate around half of the ideal gains and could be deemed sufficiently beneficial during an initial phase. After consumers gained experience with dynamic pricing, they should be transferred to the more complex and efficient schemes, though. Focussing on the installation of automation equipment could be another way to improve the efficiency of response. As this would require investments, the question of risk involved in generating benefits from demand response becomes more relevant. Using a stochastic price model the thesis shows that risk-averse investors might require a significant cost reduction, resulting in lower levels of investment in automation than what could be expected based on average prices. A policy intervention could be considered to initialise adoption, depending on the further technology cost development. Overall, the thesis improves the understanding of the specific challenges that policymaking faces when aiming at better utilisation of demand-side flexibility. It includes aspects that often would remain unaddressed in the evaluation of policies. On that basis, it provides support to the development of a coherent policy strategy for flexibility that is required for the successful transition to a fossil-free energy system.
This paper investigates the societal implications of Sustainable Energy Action Plans (SEAP) at the local community level on the environmental, social and economic dimensions of sustainability. SEAP is based on the Covenant of Mayors that is the mainstream European movement involving local and regional authorities, voluntarily committing to increasing energy efficiency and use of renewable energy sources on their territories. By their commitment, Covenant signatories aim to meet and exceed the European Union 20% CO2 reduction objective by 2020. However, the local governments have trouble in managing this crucial goal because they have to combine it with the improvement of quality of life, wellbeing and local economic development. Moreover, the complexity of political strategies are increased by specific budget requirements, considering in particular the presence of different budget constraints at the local level (e.g. internal stability agreement) and the reduction of the budget available due to the economic crisis. For this reason there is a need to develop tools able to assess the effects of environmental and energy policies on the socioeconomic system and to assist policymakers in identifying the most effective choices.

Political ecology as perspective in analyses of crises in sustainable transition: The case of on-shore wind power in a frontrunner country

This paper investigates the societal implications of Sustainable Energy Action Plans (SEAP) at the local community level on the environmental, social and economic dimensions of sustainability. SEAP is based on the Covenant of Mayors that is the mainstream European movement involving local and regional authorities, voluntarily committing to increasing energy efficiency and use of renewable energy sources on their territories. By their commitment, Covenant signatories aim to meet and exceed the European Union 20% CO2 reduction objective by 2020. However, the local governments have trouble in managing this crucial goal because they have to combine it with the improvement of quality of life, wellbeing and local economic development. Moreover, the complexity of political strategies are increased by specific budget requirements, considering in particular the presence of different budget constraints at the local level (e.g. internal stability agreement) and the reduction of the budget available due to the economic crisis. For this reason there is a need to develop tools able to assess the effects of environmental and energy policies on the socioeconomic system and to assist policymakers in identifying the most effective choices.
Post-Malthusian Dynamics in Pre-Industrial Scandinavia

Theories of economic growth hypothesize that the transition from pre-industrial stagnation to sustained growth is associated with a post-Malthusian phase in which technological progress raises income and spurs population growth while offsetting diminishing returns to labor. Evidence suggests that England was characterized by post-Malthusian dynamics preceding the Industrial Revolution. However, given England's special position as the forerunner of the Industrial Revolution, it is unclear if a transitory post-Malthusian period is a general phenomenon. Using data from Denmark, Norway and Sweden, this research provides evidence for the existence of a post-Malthusian phase in the transition from stagnation to growth in Scandinavia.

Uncertainty represents one of the key challenges in product development (PD) projects and can significantly impact a PD project's performance. Risks in PD lead to schedule and cost over-runs and poor product quality [Olechowski et al. 2012]. Risk management is one response for the identification and management of risks. Acknowledging the increasing societal and business criticality of product development projects, there is a need to more thoroughly explore the various fundamental approaches to describe and quantify various types of uncertainty as part of the overall decision making process. Decisions made by PD managers and engineers have a significant impact on the strategic value of the asset delivered, and these decisions depend on the quality of information on which they are based [Eweje et al. 2012].

Uncertainty plays an important role in decision making. Decision making quality improves if uncertainty is carefully addressed (e.g. [Prelec and Loewenstein 1991], [Riabacke 2006]). In the risk management community there is a strong argument that at least two distinct types of uncertainty have to be taken into account: aleatory and epistemic. Epistemic uncertainty arises due to lack of knowledge and can be reduced by collecting and acquiring new knowledge. This is in contrast to aleatory uncertainty that is of stochastic nature, and therefore cannot be reduced, but can be well modelled and described by probability distributions. In addition to uncertainty, ambiguity needs to be considered that addresses the different ways in which factual statements may be interpreted by different individuals [Klinke and Renn 2002]. [Flyvbjerg 2007] observed that the main challenges of large projects, including PD projects, are inadequate, unreliable or misleading information; and conflicts between decision making, policy and planning. It has been proven by empirical studies (e.g. [Levi 1990], [Sahlin 2012]) that the amount and quality of information behind probabilities and utilities is an important factor when making decisions, in other words, people tend to make different decisions if they are aware of the amount and quality of the data on which probability and utility assessments are based. Arguably, the key challenge in PD risk management today is that uncertainty quantification relies solely (or at least heavily) on probabilistic models. While these are appropriate to describe aleatory uncertainty, they are fundamentally ill-suited to model epistemic uncertainty. In this paper, we will explore novel post-probabilistic uncertainty quantification models that promise to better address epistemic uncertainty, and their possible application in the context of PD risk management.

Prediction of Repair Work Duration for Gas Transport Systems Based on Small Data Samples
Prediction of the duration of a repair and maintenance project of a gas transport system is an important part of planning activities. There exist numerous sources of uncertainties that may result in time overruns possibly leading to multiple negative consequences. Our experience in planning this work suggests that accepting the stochastic nature of the project duration is a constructive step towards the preparedness to contingencies and defining penalties for repair companies. To support this approach, one needs to construct probability distributions of the durations of the projects. To address the issue of the scarcity of observed data, we suggest using a bootstrap resampling procedure. Gram-Charlier functions and order statistics are employed to approximate the distributions. It is demonstrated how to derive them for a separate repair project and a larger project consisting of a number of concurrently running subprojects. Following this, guidance is provided on how to decide about what duration should define the deadline for completion of the whole work. A simple example is provided.

Prevention of "simple accidents at work" with major consequences

The concept "simple accidents" is understood as traumatic events with one victim. In the last 10 years many European countries have seen a decline in the number of fatalities, but there still remain many severe accidents at work. In the years 2009–2010 in European countries 2.0–2.4 million occupational accidents a year were notified leading to 4500 fatalities and 90,000 permanent disabilities each year. The article looks at the concept "accident" to find similarities and distinctions between major and simple accident characteristics. The purpose is to find to what extent the same kinds of prevention or safety methodologies and procedures established for major accidents are applicable to simple accidents. The article goes back to basics about accidents causes, to review the nature of successful prevention techniques and to analyze what have been constraints to getting this knowledge used more broadly. This review identifies gaps in the prevention of simple accidents, relating to safety barriers for risk control and the management processes that need to be in place to deliver those risk controls in a continuously effective state. The article introduces the "INFO cards" as a tool for the systematic observation of hazard sources in order to ascertain whether safety barriers and management deliveries are present. Safety management and safety culture, together with the INFO cards are important factors in the prevention process. The conclusion is that we must look at safety as a part of being a professional in all kinds of jobs and occupations as well as at management level. © 2015 Elsevier Ltd. All rights reserved.

Process Risk Assessment using Dynamic Simulation of Scenarios

Process plants may be very complex and may combine various processes in close proximity. Hence, the response to accidents may easily grow complex. Traditionally, after gathering and getting acquainted with the plant's technical information, risk is analysed in prescribed steps starting with hazard identification, description of accident scenarios and using the conventional approach to develop static event trees for events following a loss of containment. Modelling the impacts and consequences needs models to describe the release, dispersion and effect of the hazardous material, as well as models for predicting the egress time of people, response times of detectors and other safety equipment. A common assumption is the independence of these models and their sequential treatment, but often the consequences and effects are mutually dependent. The prediction of the consequences and effects are deterministic assignments applying simplified engineering models with averaged/expected values as input to account for the characteristics of the system, e.g. describing the physical and environmental phenomena and workers responses. The size of the release and dispersion depends on technical and environmental parameters. Ignition sources may be permanent or temporarily present at various locations near the release. The response times of detectors may be dependent on the velocity of cloud spread. The available save egression time depends on these parameters. Such dynamics are easily modelled using Discrete Event Simulation (DES) of the scenarios, which is a Monte Carlo type method.

The paper describes the application of DES to conduct the analysis part of a risk assessment that enables better time resolution in the modelling of the specific scenarios, simulate the interactions between concurrent chains of events under the hazardous scenarios, and produce probabilistic risk measures. The outcome provides possibilities to structure the results in a comprehensive way. Scenarios with severe consequences can be ‘played back’ to learn from them and can be animated, which apart from the learning effect provides a new way of validation.

Product configuration system and its impact on product’s life cycle complexity

The purpose of this paper is to identify areas throughout a product's lifecycle processes where complexity can be reduced by implementing a product configuration system (PCS). As discussed in the literature, several benefits are realized by using a PCS in terms of product and process standardization. This also leads to control and reduce of complexity both in products and processes. To this end, this research attempts to quantify and assess these benefits and is supported by empirical evidence. A case study of an engineering company is used and the results indicate significant improvements for the company in several life cycle processes.
This paper reports from a study exploring the internal Occupational Health and Safety (OHS) management in Danish companies. The results indicate a tendency towards professionalization, where employees are employed specifically with the purpose to manage and coordinate Health and Safety activities. In this manner the companies are ensured access to OHS knowledge. The role as OHS professional may either supplement or, in some cases, take over from the employee-elected health and safety representatives (HS reps) and the internal health and safety organization. The interviewed OHS professionals had different approaches to their work, thereby representing different directions in the corporate work environment. In this article we examine what characterized the different approaches to the role of the OHS professional. We focus specifically on the relationship between the role of OHS professional and the elected HS reps. We introduce three different approaches to the role of OHS professional – ‘the system builder’, ‘the process oriented’ and ‘the operations oriented’ OHS professional. These three approaches represent fundamentally different understandings of the role of the employee-elected HS reps and the OHS committees, which the Danish OSH legislation requires the company to implement. Both ‘the system building’ and ‘the operations oriented’ OHS professional have a tendency to monopolise all the OHS activities leaving the role of employee elected HS rep as an empty formality without powers or duties associated with OHS management, thereby removing initiative and commitment from the HS reps.
Profile and Trends of FTA and Foresight

This chapter presents the profile and trends of the academic discipline of Future-oriented Technology Assessment (FTA) and its approaches. This chapter presents the profile and trends of the academic discipline of FTA and its approaches. This is achieved through analyses of the development, focus and scientific impact of FTA. As such, this chapter contributes to the discussion on the conceptual development and academic positioning of FTA (or Foresight). The chapter is based on bibliometric analyses of the special issues of five international journals published after the FTA conferences in 2004, 2006, 2008 and 2011: Technological Forecasting and Social Change, Futures, Technology Analysis and Strategic Management, Science and Public Policy, and Foresight. Methodologically, the paper draws on the principles of Elsevier’s Scopus and Thompson Reuter’s Web of Science. The chapter concludes that the field of FTA seems to have remained remarkably stable over the last decade. As an academic field, FTA has targeted a small number of journals for its publications, which has helped to further define and focus the field. Finally, the chapter concludes that publications in special issues of international journals resulting from the FTA conferences have a similar level of quality and scientific impact as articles published in standard issues of these journals.

Project studies and engaged scholarship: Directions towards contextualized and reflexive research on projects

Purpose
In 2006, the “Rethinking Project Management” network called for a paradigm shift in project research, and proposed five research directions. The directions inspired research and marked a milestone in the development of the field. The purpose of this paper is to reflect on the past decade and to rejuvenate these research directions.

Design/methodology/approach
The authors propose the umbrella term: “project studies” to denote the research related to projects and temporary organizing. Project studies is conceived not only as a body of research, but also as a social process embedded in research communities, and contemporary Zeitgeist. Based on Sandberg’s interpretative approach to the fit between work and works (in this case research-researcher) and Habermas’ three types of human interests: technical, practical, and emancipatory, the authors develop a conceptual framework circumscribing three types of research in project studies.

Findings
The conceptual framework is used to craft future research directions, in the lines proposed by Winter et al. (2006b). Research limitations/implications
The authors conclude by proposing for a sixth theme on the practice of theorizing, and call for engaged, ambidextrous scholars, who’s “job” goes beyond the writing of articles and research applications, and includes shaping discourses of
project research, nurturing new project scholars, contributing to project practice and carefully considering the legacy of projects and project studies in society.

Originality/value
This paper positions research as a social process, and the role of researchers as actors shaping research in project studies.

Projektbølger - Effektiv projektmødel for organisatoriske udviklingsprojekter på hospitaler
Der startes mange projekter på de danske hospitaler og en stordel af dem opnår ikke de ønskede resultater. På baggrund af evaluering af 11 delprojekter i Region Nord og på Glostrup Hospital foreslår jeg at projekter samles og startes sammen i bølger og beskriver en overordnet projektmødel samt udlederen række principper for projektbølger. Projektbølger skaber fokus, fremdrift og erfaring på tværs af delprojekter og er en ny måde at tænke på på danske hospitaler.

Prototyping with your hands: the many roles of gesture in the communication of design concepts

There is an on-going focus exploring the use of gesture in design situations; however, there are still significant questions as to how this is related to the understanding and communication of design concepts. This work explores the use of gesture through observing and video-coding four teams of engineering graduates during an ideation session. This was used to detail the relationship between the function behaviour structure elements and individual gestures as well as to identify archetypal gesture sequences – compound reflective, compound directed one-way, mirroring, and modification. Gesture sequences occurred at critical periods during the design session, such as idea evolution and developing shared understanding. They are used to act out design concepts, repeat and learn from sequences, and establish shared understanding. Finally, a number of implications are identified for both researchers and those seeking to support practice.

Proximity search heuristics for wind farm optimal layout

A heuristic framework for turbine layout optimization in a wind farm is proposed that combines ad-hoc heuristics and mixed-integer linear programming. In our framework, large-scale mixed-integer programming models are used to iteratively refine the current best solution according to the recently-proposed proximity search paradigm. Computational results on very large scale instances involving up to 20,000 potential turbine sites prove the practical viability of the overall approach.

Quantification of Benefits and Cost from Applying a Product Configuration System

This article aims at analyzing the long-term benefits and the cost from developing, implementing and maintaining product configuration systems (PCSs). The results presented indicate that over 5 years period a case company has achieved significant savings as a result to reduced workload of generating the products' specifications. In addition the lead-time for generating products' specifications has been reduced and indications of improved quality of the products' specifications and additional sales are identified. The research verifies the benefits described in the current literature and contributes by linking the benefits to the direct cost savings companies can expect from utilizing PCSs.

Reactive or proactive approach towards sustainability? A conceptual framework based on sustainable business models to increase stakeholders' sustainable value capture

Indications towards the need for development and implementation of solutions for more sustainable development are not recent. However, the world is still struggling to tackle these challenges, and sustainability is not an optional agenda, but rather it is an obligatory and necessary issue for the various actors in society. This is also valid for organizations, which are expected to assume a more proactive and entrepreneurial posture towards tackling sustainable development challenges. In this sense, sustainable business model approach can support organizations to be more sustainable, serving as instrument to help companies describe, analyze, manage and communicate their sustainable value proposition, creation, delivery and capture mechanism. In particular, this research focuses on value capture dynamics, aiming to explore how companies can increase their contribution to sustainable development by fostering sustainable value capture of their stakeholders. Thus, we bring a literature review to discuss the mechanism of two approaches: the reactive and proactive approach. The first logic is about satisfying stakeholders' needs and wants, reacting to their demands. A more reactive approach to stakeholders' expectations is supported by motivations derived from marketing, corporate social responsibility, international standards, sustainability reporting, labelling, etc. However, these demands are not always aligned with sustainability, creating tensions between stakeholder satisfaction and corporate sustainability. In this sense, a proactive approach to foster sustainable value capture can complement the reactive approach by delivering value beyond stakeholders' expectations. In this case, companies use their capabilities to identify opportunities to create and deliver sustainable value that stakeholders were not expecting or demanding, but that are positive in terms of sustainability. The proactive approach on managing stakeholders finds its justification on questioning companies about their institutional role in society, demanding sustainability innovation in companies' business models and challenging companies to seek for business opportunities with an entrepreneurial attitude to help solving sustainable development challenges. By combining both approaches, organizations have the opportunity to increase sustainable value capture by its stakeholders, acting on their institutional responsibility as actors in the societal system. Thus, future researches are invited to contribute to further theoretical and empirical discussions to explore the potentials of fostering sustainable value capture.

Realising the potential of shared space in facilities management

As a global society, we have passed the pivotal point and more than half of the earth’s population now live in cities, with more and more people making the choice to live in cities each day. Though the large urban communities resulting from this population migration come with many advantages, the growing cities of Europe as well as the world face numerous challenges. An essential one is that the population redistribution can make it difficult to provide adequate space for the population, since people moving to cities means an increased population that needs a myriad of different facilities, and spaces to accommodate these functions to make city-life work. Urban development and development of new city profiles has traditionally been focused on building new, but with increasing populations, urban space for new buildings will inevitably become increasingly scarce and expensive. So, with physical constraints and still challenging economic circumstances, just building new is not always an option – or desirable. We must therefore start rethinking the city, and this is where shared space has the potential to play a role.

Shared space is a collective term for space and facilities that are shared between individuals or groups from different organisational contexts, and this PhD investigates the intricate processes concerning shared space in a facilities management context. The overall aim is divided in a theoretical and a practical part, with the theoretical focused on contributing with new knowledge of shared space, building towards a new method for efficient and sustainable facilities management operation of buildings and properties. The practical part is focused on connecting this new knowledge to practical applications and developing tools that can be used to work with shared spaces in a practice.

Grounded in literature from a variety of fields stretching from facilities management to urban planning and development, this PhD adopts a qualitative approach to the study of the intricate processes involved in working in, and with, shared space. The study employs case studies as the method of choice for answering the research question set forth, backed by empirical data collected through interviews, observations, workshops and surveys, and supported by literature and case relevant documents.

Overall this dissertation and the PhD project behind it offer several contributions to both academia and practice. With base in literature, the empirical data and through thorough analysis of the many different cases studied throughout the PhD, a typology of shared use of space and facilities and a guide to shared space in municipalities have been developed. The typology categorises shared spaces in three main categories according to degree of sharing, and lists a number of characteristics of shared spaces to provide a starting point for discussing, developing and working with shared space in both academia and practice. The guide on the other hand synthesises the theoretical knowledge resulting from the study in general, as well as the work having gone in to the development of the typology, and combines it with a number of practical steps to be taken co-created with practitioners. Through this combination it presents a complete guide to working with shared space in a municipal real-estate portfolio, from identifying potential on a portfolio level to evaluating the final result after the space has been taken into use.

Through the process of identifying these key aspects of shared space and the study of the intricate processes involved, three themes, territoriality, involvement and practicalities, were identified as essential when working with shared space, and these in combination with the typology and the guide described, are the final result of the study.

The work conducted throughout the PhD is published in five scientific papers and are summarised in this dissertation. The research contributes to both theory and practice, and adds to the so far very limited knowledge on the topic.

Real-time thermal imaging of solid oxide fuel cell cathode activity in working condition

Electrochemical methods such as voltammetry and electrochemical impedance spectroscopy are effective for quantifying solid oxide fuel cell (SOFC) operational performance, but not for identifying and monitoring the chemical processes that occur on the electrodes’ surface, which are thought to be strictly related to the SOFCs’ efficiency. Because of their high operating temperature, mechanical failure or cathode delamination is a common shortcoming of SOFCs that severely affects their reliability. Infrared thermography may provide a powerful tool for probing in situ SOFC electrode processes and the materials’ structural integrity, but, due to the typical design of pellet-type cells, a complete optical access to the electrode surface is usually prevented. In this paper, a specially designed SOFC is introduced, which allows temperature
distribution to be measured over all the cathode area while still preserving the electrochemical performance of the device. Infrared images recorded under different working conditions are then processed by means of a dedicated image processing algorithm for quantitative data analysis. Results reported in the paper highlight the effectiveness of infrared thermal imaging in detecting the onset of cell failure during normal operation and in monitoring cathode activity when the cell is fed with different types of fuels.

Recommendations on the role of auctions in a new renewable energy directive

During the work in the AURES project, we have found evidence that auctions can be a suitable instrument for allocating support under budget and volume limitations and can achieve significant short-term efficiency gains, but it has not been proven that auctions in general are better suited to support renewable energy than other support instruments. The use of auctions entails several new implications that often policy makers have not had to deal with before: ensuring sufficient competition for a well-functioning price formation, avoiding undesired strategic incentives, collusion and other market distortions, and importantly dealing with risk of low realisation rates, e.g. caused by underbidding or the existence of non-cost barriers. Often, the specific design solutions for these issues are highly context-specific and what works in one market is not necessarily applicable to another. In addition, different design elements might mitigate some issues but affect other factors, e.g. pre-qualification rules and penalties can increase realisation rates but can also increase the risk and thus the costs for bidders. In addition, policy makers often pursue other policy goals (secondary objectives) with energy support policy, e.g. increasing security of supply or encouraging actor diversity. Finding a compromise between encouraging different policy goals without compromising on well-functioning price formation, proves to be a challenging task. Overall, auctions are only just emerging as instrument for allocating support of renewables and experiences so far are rather limited and mixed.

Reconfiguring Variety, Profitability, and Postponement for Product Customization with Global Supply Chains

At present, many industrial companies offering high product variety focus on systematically reducing the complexity of their product range and business processes. Related challenges are often named to increase time to market, reduce the effectiveness in product development, and lower process efficiency. For manufacturers with global supply chains additional uncertainties arise in defining the right manufacturing strategy with respect to production location and postponement. To better understand related managerial implications, this paper discusses a case study a global manufacturer providing customized industrial applications. In particular, the study investigates the relationships between product variant profitability and manufacturing strategy relative to postponement and location. The results indicate that an
improved configuration of these factors through substitution and supply chain redesign significantly increases the overall product portfolio profitability.

**Recurring themes in the legacy of Jens Rasmussen**
The work of Jens Rasmussen over the course of the last half century represents some of the most influential contributions to the fields of cognitive science, human factors, ergonomics and safety science. His work has inspired researchers and practitioners in a number of fields including psychology, organisational behaviour, engineering and sociology (Le Coze, 2015). Early work on the Skills, Rules, and Knowledge taxonomy for example, was instrumental in fostering the development of models of human error during the 1980s and 90s (e.g. Norman, 1981; Reason, 1990). In more recent years, a large amount of research has drawn on theoretical and practical aspects of Rasmussen's work including his models of the boundaries of safe operation, ecological interfaces and methods such as cognitive work analysis. Rasmussen's work on the Risk Management Framework (Rasmussen, 1997) has been cited over 1000 times since its original publication in 1997 and the extent of his influence across the wider research community is growing at a fast rate (Wears, 2015). His research has taken on renewed relevance and importance in the light of recent large-scale systems disasters and accidents (e.g. Fukushima Daiichi, Deepwater Horizon, and South Korea Ferry Disaster), as well as recent developments in the fields of normal accident theory (Perrow, 1984), resilience engineering (Hollnagel et al., 2006) and the high reliability organisation (Weick and Sutcliffe, 2007; Le Coze, 2016a).

Re-designing the everyday; The use and perception of time among cancer patients combining work and treatment

This article describes how time was used dynamically by a group of people at risk of losing their lives. It is shown how these people appeared to experience a change in the relationship between inner and outer time and that time literally was felt in this situation. An empirical investigation of 16 cancer patients performing their jobs while going through demanding treatment programs found time as their main motive for working while being seriously ill. Actions at work point to a time ahead, so by taking part in the time at the workplace they were inscribed in a future presently under pressure by their cancer diagnosis. The article describes how cancer struck women and men perceived time in their different life-worlds, at work, at home on temporary sick leave, and at the hospital, and it shows how these perceptions changed during the process of recovery. To these people time appeared in three forms: A time beyond control, realizing that they had cancer; taking control of time, discovering that they could go to work; the time of the future, which was their new perception of time as cured. This new perception of time reflected the incidental discovery of the cancer, realizing life as coincidental. Having their life time threatened made them feel vulnerable and liminal (neither sick nor well, but on the way to recovery). This vulnerability can be seen as the result of a breakdown of our taken-for-granted space-time world. For these people, going to work seemed to reduce the unbearable waiting time towards recovery by re-establishing links to a well-known life-world, the workplace.

Regional foresight and dynamics of smart specialization: A typology of regional diversification patterns

The concept of smart specialization has attracted great interest and has been adopted widely in European regional and innovation policy. Foresight is an important part of creating smart specialization strategies. However, both the smart specialization concept and foresight have been criticized for lacking an empirical and theoretical foundation that can help guide their application in practice. This paper contributes to the theoretical foundation of smart specialization and regional foresight by drawing on the field of economic geography and elaborating a typology for patterns of smart specialization. We highlight that there are different paths to reaching smart specialization within the same industrial domain. The empirical research focuses on the offshore wind service sector in four regions around the North Sea. The findings corroborate a typology that offers four distinct patterns—diversification, transition, radical foundation, and modernization—all of which can enable the creation of new industrial activities where regions enter an emerging industry based on fundamentally different starting points.
Large share of variable renewable energy sources (VRE) is being deployed in the Nordic countries, especially wind power. This calls for additional flexibility of the power market. With the right coupling to the underlying national and local district heating (DH) markets, large shares of flexibility can be generated. However, regulatory barriers and different energy taxes may hinder the potential benefits from systems integration and lower the realisable potentials. By a case study for Denmark we survey and discuss regulatory barriers and drivers for flexibility obtained from DH. We reveal that the choice of technologies for heat generation is mainly driven by outdated policies and tax conditions that create barriers for additional flexibility in the overall energy system. However, the balancing markets may be a main driver for introducing more electric boilers into DH and thereby increase its contribution to flexibility.
implications of the interorganizational relationships is studied through a theoretical framework of modularity by looking for variance and repetition. The analysis shows that the projects are designed for each specific location (region) with unsystematic and limited use of processual, organizational and technical repetitions. Overall, the projects are executed in parallel and follow the same phases with a high degree of user involvement in each of the projects; here inputs are gathered for the specific project that subsequently is designed by a unique team of architects and consultants. Although some of the participating companies are involved in several projects (especially as the client consultant), there is a high degree of variance in the project teams. Despite the variance of the project teams the overall and detailed design of the hospitals look remarkably the same. However, a detailed analysis of the patient rooms reveals that although 70% of the projects use the same archetype (the L-type) they are different from each project. This lead us to the conclusion that the hospital is reinvented in each project leaving behind unrealized potential for leveraging similarity across the projects. This could have been achieved by a stronger central coordination, thinking of super hospitals as programs and portfolios rather than individual projects.

Residential heat pumps in the future Danish energy system

Denmark is striving towards 100% renewable energy system in 2050. Residential heat pumps are expected to be a part of that system. We propose two novel approaches to improve the representation of residential heat pumps: Coefficients of performance (COPs) are modelled as dependent on air and ground temperature while installation of ground-source heat pumps is constrained by available ground area. In this study, TIMES-DK model is utilised to test the effects of improved modelling of residential heat pumps on the Danish energy system until 2050. The analysis of the Danish energy system was done for politically agreed targets which include: at least 50% of electricity consumption from wind power starting from 2020, fossil fuel free heat and power sector from 2035 and 100% renewable energy system starting from 2050. Residential heat pumps supply around 25% of total residential heating demand after 2035. The improved modelling of residential heat pumps proved to have influence on the results. First, it would be optimal to invest in more ground-source heat pumps, but there is not enough available ground area. Second, the total system costs are higher when COPs are modelled as temperature-dependent compared to fixed COPs over a year.
Restoration of abraded and covered marks engraved in steel using active infrared thermography

Alphanumeric marking is a common technique employed in industrial applications for identification of products. However, the realised mark can undergo deterioration, either by extensive use or voluntary deletion (e.g., removal of identification numbers of weapons or vehicles). For recovery of the lost data many destructive or non-destructive techniques have been endeavoured so far, which however present several restrictions. In this paper, active infrared thermography has been exploited for the first time in order to assess its effectiveness in restoring paint covered and abraded labels made by means of different manufacturing processes (laser, dot peen, impact, press and scribe). Optical excitation of the target surface has been achieved using pulse, lock-in and step heating. Raw infrared images were analysed with a dedicated image processing software originally developed in Matlab (TM), exploiting several methods, which include thermographic...

Revenue in reverse? An examination of reverse supply chain enabled revenue streams

When original equipment manufacturers (OEMs) examine whether to implement a reverse supply chain (RSC) for their products, oftentimes the motive is cost savings or regulatory compliance. However, a frequently overlooked but equally important benefit is the possibility for creating new revenue. The purpose of this paper is to examine which revenue streams the RSC enables for OEMs to utilize and how these streams are utilized in industrial practice. First, the paper identifies the RSC-enabled revenue streams that are available to OEMs using a literature-based conceptual modeling approach. Second, using a set of eight cases the paper explores these streams’ utilization pattern and develops a set of propositions that explain the pattern. Results show a set of 12 distinct RSC-enabled revenue streams within three categories: new revenue through sales of used items, new revenue through sales of recovered items, and new revenue through added sales of virgin products. Six of these 12 streams are utilized in industrial practice. Among the propositions that explain the utilization pattern are the degree of component customization, product life-cycle longevity, and the value gap between used and recovered products. While extant literature concerning the relation between the RSC and the firm’s revenue is scarce, this paper contributes to the understanding of RSCs’ revenue generation potential and thus to the stream of literature that views the RSC as a value creator rather than a costly nuisance. Furthermore, the paper provides managers with a broad view of how their firm’s RSC can increase revenue from existing markets as well as create...
Ringkøbing-Skjern energy atlas for analysis of heat saving potentials in building stock

Ringkøbing-Skjern municipality aims to be 100% self-sufficient in renewable energy supply starting from 2020. It is expected that the building sector will contribute by reducing energy demand by 25-50%. Technical, economic, environmental and geographical aspects need to be considered when analysing such drastic change of municipality’s energy system. For that purpose, GIS-based Ringkøbing-Skjern Energy Atlas has been developed. The present paper...
utilises Ringkøbing-Skjern Energy Atlas together with the Heating Model to calculate potentials and costs of heat saving measures. The results show that the reduction of heating demand by 25% and 35% can be achieved at the annuitized full cost lower than 1.7 and 2 DKK/kWh, respectively. The results also show that significant heat saving potential lies in farmhouses and detached houses as well as in buildings built before 1950. Over 75% of very cheap heat saving potential can be harvested by insulating floors, while majority of heat saving potential cheaper than 2 DKK/kWh can be utilised by insulating floors and installing mechanical ventilation systems. After heat savings and heat supply options are compared from a private-economic perspective, it is concluded that heat savings should be directed towards buildings supplied by oil boilers, natural gas boilers and ground-source heat pumps.

Risk implications of investments in demand response from an aggregator perspective

Aggregators are expected to play an important role in making households provide flexibility to the electricity system. We investigate the business case of aggregators offering a demand response product in a competitive retail market, then directly accessing their customers’ flexibility through remotely controlled demand response devices and marketing it on the
electricity markets. As the value of flexibility largely relies on price variations, we use a stochastic electricity price model, which we combine with a linear optimisation program and a cash-flow model to determine expected operating gross margins and their probability distributions. We find that, for a case of Danish residential customers with optimistic assumptions on the available flexibility in terms of flexible volumes and load-shift time horizons, the benefits may be in the range of current investment cost for automation equipment. Furthermore, a Value-at-Risk analysis shows that income expectations are rather stable with more upside than downside potential. With foreseeable cost reductions for smart devices the aggregator business case might soon become attractive, particularly in markets with high shares of renewable production.

Safe and Sustainable: Optimizing Material Flows in a Circular Economy
Increasing the sustainability of a globally connected economy is gaining wide attention in a world with limited natural resources and growing chemical pollution. The circular economy has emerged as away to reduce carbon and other emissions, while increasing resource efficiency over several product life cycles. However, a circular economy is only viable if it is both safe and sustainable. The dilemma is that sustainable does not necessarily imply safe and vice versa. When minimizing exposure to harmful chemicals in consumer products (safe), we often use more energy-demanding alternative solutions (unsustainable). When maximizing resource use efficiency and reducing carbon and other emissions through recycling (sustainable), direct consumer exposure is often increased through cross-contamination of recycled materials (unsafe). Hence, circular economy currently fails to unite the required expertise to simultaneously increase sustainability and reduce exposure to chemicals in materials reused across life cycles of different products. For a way out of this dilemma, a paradigm shift is needed towards a comprehensive and quantitative assessment framework.

Sectoral Patterns of Eco-innovation: Theoretical considerations and a study case in the automotive sector

There goes almost thirty years since the World Commission on Environment and Development released the Our Common Future report, more than four decades since the Jay W. Forrester’s Institute at MIT launched Limits to Growth, and more than two centuries since Thomas Malthus first published An Essay on the rinciple of Population, all calling attention to the limits of natural resources, but the humanity – and particularly the Homo economicus – still struggle to acknowledge the limitations of our planet and act upon it. We appear to be locked in a primitive, tribal-oriented mindset, unable to effectively think and act globally. In this perspective, the academic community is still taking the first steps towards the understanding of what a “green” economy - or more widely, a green society - truly means and how to move our whole industries, our habits, and our mindsets in that direction.

Seeing the city: photography as a place of work

During the Futurescape City Tours, sponsored by the Center for Nanotechnology in Society, citizens engaged in an urban walking experience that involved observing, documenting and deliberating about the past, present and future of technology in the urban environment. Central to this experience was the use of photography as the place of work where the citizen-photographers created a visual language to grant meaning and structure to their experience and deliberations. Drawing on Barthe’s (1980) idea of semiology as a construction of meaning through the exploration and identification of systematic regularities of signs and objects, as well on Benjamin’s (1999) notion that there is no photography without discourse, this paper demonstrates what these individuals see as their relationship to their city as portrayed through photographic observations. This paper aims to empirically illustrate the uses and power of an image to mediate discourse and representations of technological change in the city. Further, it opens a scholarly conversation on role of visual cultures in the construction of the necessary capacities among individuals to critically reflect on their role as technological citizens toward better understanding pathways to sustainability. To do so, we conducted a visual ethnography of the participants’ photographic images and captions. By pushing the boundaries of photography beyond an artistic practice into the realm of public engagement, we demonstrate the ways in which “a camera is a tool for learning how to see without a camera,” as Dorothea Lange once stated.

Segregated Debate on Biofuels in Ghana? Options for Policymaking

Biofuels has been an increasingly debated issue since the beginning of this century. Some scholars emphasize the risks of biofuels on livelihood in Ghana; while others argue positively for the rural development and energy security potential of biofuels. These serve as the rationale of this study. This objective was to investigate ambivalence in the scholarly discourse on biofuels for Ghana. It also assessed the implications of the present dichotomy of scholarly opinion on policy making by government. The study employed a systematic methodology and search strategy that made use of database searches in the scholarly and grey literature published recently by using the search terms „biofuel“ and „Ghana“. The findings show a major skepticism - optimism divide in the biofuel discourse and its potential to improve livelihoods in Ghana. This study attempts to describe this dispute by quantifying different scholars” position on a scale from pessimist to optimist. This is not meant to be reductionist or over simplistic, but rather the work we have done provide an illustrative perspective and overview of the scholarly divisions and gaps. Findings suggest that the biofuel discussions would benefit greatly from less segregation of effort and increased collaboration especially among scholars from opposing schools of thoughts. This would possibly help to provide invaluable information required by decision makers. Findings also suggest the possible use (in the absent of clear consensus), of information by knowledge networks including the GBEP, RSB, GNESD among others.

Sensitivity analysis of the use of Life Cycle Impact Assessment methods: a case study on building materials

The main aim of this research is to perform a sensitivity analysis of a Life Cycle Assessment (LCA) case study to understand if the use of different Life Cycle Impact Assessment (LCIA) methods may lead to different conclusions by decision makers and stakeholders. A complete LCA was applied to non-load-bearing external climate walls for comparative purposes. The LCIA phase of the case study was performed using five different Impact Assessment Methods: EDIP 97/2003 (midpoint), CML 2001 (midpoint), Impact 2002+ (endpoint and midpoint), ReCiPe (endpoint and midpoint) and the ILCD recommended practices for LCIA (midpoint). The endpoint results were compared aggregatedly, and the midpoint categories concerning similar potential impacts were compared individually for the analysis of possible deviations. The observations and comparisons involved mostly the decision maker's point of view and not the differences among the characterization models. The endpoint LCIA showed that the only two methods which applied such an approach (Impact 2002+ and ReCiPe) provided different results and led to different conclusions. For midpoint LCIA, the results were completely consistent for the following impact categories: General Eutrophication, Aquatic and Freshwater Ecotoxicity, Ionizing Radiation, Particulate Matter Formation, and Resources Depletion. Global Warming, Terrestrial Ecotoxicity, Human Toxicity (except for the Non-carcinogens impact category) and Land Use (except for Natural Land Transformation) showed partially consistent results and pointed out to the same worst environmental alternative, but with a slightly different impact profile among the other alternatives. Ozone Layer depletion and Photochemical Oxidant Formation categories showed discrepant results and the impact profile differences between the older and newer methods were notable. Acidification, Terrestrial and Aquatic Eutrophication, Marine Ecotoxicity and Water Depletion showed substantially inconsistent results. (C) 2015 Elsevier Ltd. All rights reserved.
Shuttle Planning for Link Closures in Urban Public Transport Networks

Urban public transport systems must periodically close certain links for maintenance, which can have significant effects on the service provided to passengers. In practice, the effects of closures are mitigated by replacing the closed links with a simple shuttle service. However, alternative shuttle services could reduce inconvenience at a lower operating cost. This paper proposes a model to select shuttle lines and frequencies under budget constraints. We propose a new formulation that allows a minimal frequency restriction on any line that is operated and minimizes passenger inconvenience cost, which includes transfers and frequency-dependent waiting time costs. This model is applied to a shuttle design problem based on a real-world case study of the Massachusetts Bay Transportation Authority network of Boston, Massachusetts. The results show that additional shuttle routes can reduce passenger delay compared to the standard industry practice, while also distributing delay more equally over passengers, at the same operating budget. The results are robust under different assumptions about passenger route choice behavior. Computational experiments show that the proposed formulation, coupled with a preprocessing step, can be solved faster than prior formulations.

How to improve the utilization of a Configuration Lifecycle Management (CLM) system

The aim of the post-doc project is to add to the theory on scoping and setting up Configuration Lifecycle Management (CLM) systems and to study the potential benefits of applying them. A CLM-system supports the management of multi model configurations, as it covers the application of product configuration in all the different life cycle phases of a complex and highly engineered product.

Department of Management Engineering
OLCA-Pest
The main objective of the OLCA-Pest project is to build on current advances in life cycle inventory and life cycle impact assessment to operationalise and harmonize the emission quantification and impact characterization of pesticides in life cycle assessment (LCA) and product environmental footprinting. In current LCA practice, quantifying pesticide emissions from agricultural fields is not aligned with characterising related potential toxicological impacts on humans and different types of ecosystems. Furthermore, the pathways from pesticide application via emissions to environmental media and treated field crops to toxicity impacts are currently only partly and inconsistently covered and many relevant pesticides are currently not included. This leads to LCA results that are incomplete and often misleading and hard to interpret and this makes it impossible to assess and compare the environmental performance profiles of different pest management systems and practices.

Smart Load
The increasing capacity of container vessels is pressuring container terminals worldwide to improve their performance. Simple improvements of work practices are no longer a viable option even for the medium and small container terminals we find in Denmark. With this project we wish to initiate a pilot study on the possibility of improving terminal performance by exploiting the flexibility that arises from a possible collaboration between the terminal planners and the ship owners. A preliminary study, done in collaboration with APM Terminals – Cargo Service A/S (APMT) in Aarhus, has shown that giving the terminal some decision power over the arrangement of the containers in the vessel can result in improved vessel handling times. With this research application we wish to initiate a pilot project that can demonstrate the potential of this collaboration on an industrial scale. In order to do so, APMT has agreed to provide data and domain expertise to the research team at the Technical University of Denmark (DTU), and be an active partner in this project. The research team envision the use of operation research methods to optimize the new planning problems that arise from this collaboration.

Where does the green economy grow? The Geography Of Nordic Sustainability Transitions (GONST)
There is no one-size-fits-all approach to greening the growth path of an economy as this depends on place-based policy and institutional settings, level of development, resource endowments and particular environmental pressure points. This research proposal addresses the place-based, context-dependent nature of the shift to green growth in the Nordic countries by asking the question: where does the green economy grow? In addressing this question, we foreground the importance of innovation, new industry formation, and radical industry transformation.

The project is based on a mixed methods approach. Quantitative techniques will be applied to analyse the importance of human capital and technological specialisation for the greening of the economy. Qualitative case studies of Nordic regions will focus on the role of institutions and account for the diversity in Nordic regional green pathways.

Participating regions will benefit from a thorough analysis of current green growth processes and the opportunities for further greening. The project in particular seeks to engage pioneering green growth regions in the case study analysis, and a full work package in the project will be focusing on the possibilities for policy-learning between participating regions. An important element here will be to distinguish between those successful practices that can be transferred between regions, and those which are context dependent.

**DynaStow**  
The use of larger vessels is increasing the planning complexity of stowage coordinators. Stowage planning main goal is to find an arrangement of the containers such that time at port is minimised. In order to do so, stowage coordinators must ensure that situations where containers going to later ports are stowed on top of containers to be discharged earlier. Such containers are called overstowing containers. A worse situation appears when overstowing containers are in between hatch-covers (metallic structures dividing the upper and lower deck). In this situation, a container terminal is forced to remove all containers above the hatch, lift the hatch itself, to then finally discharge the needed containers. Such a situation is clearly undesirable. Aside from the minimization of container moves, it is also important that the stowage plans are designed for efficient port operations. Liner shippers and container terminals, often, agree on an expected cargo handling performance (often in terms of container moves per hour). Stowage coordinators must, to the best of their ability, generate stowage plans tailored to the agreed terminal performance. This is not an easy task since cargo loaded in earlier ports can have a large negative impact on handling operations in later ports. Even though those objectives in themselves are complex to achieve, stowage coordinators also need to ensure the sea-worthiness of the vessel. Weight balance, stress forces, handling of dangerous cargo and stacking constraints are but a few examples of the rules that a stowage plan must obey. The possibility of cost reduction, by use of optimisation techniques, are not small. Consider the number of containers Maersk has moved in this year’s first quarter (ca. 2.500 thousand FFU), and assume a total of just 5% of overstowing containers. A conservative price of 60,00 USD per re-stow will result in an estimated cost of 60 mils. USD. It is easy to see that even a small percent reduction of the overstowing containers would bring savings in the order of millions.

This project has two main goals:  
1. Reinforce the Danish status of being the top research country for stowage planning  
2. Produce research results that can have an impact on the Danish maritime industry

Wrt. to 1) we wish to become the main authority in terms of stowage planning research in the world. Our research results
so far have granted us the respect of many maritime researchers. As the main researchers on stowage planning we have
the responsibility of setting the correct research standard. The amount of knowledge on stowage planning of the
applicants and of the Danish maritime industry places Denmark in a unique position to do so. Wrt. 2) we believe that
applied research must have an impact. We, therefore, have engaged in a partnership with Optivation, and through them,
Seago Line (part of the Maersk consortium), to help us in guiding the project toward solutions tailored for the industry.

Project

Supporting the development of robust and comparable mitigation actions through the Mitigation Action Assessment
Protocol.
The World Bank has developed the Mitigation Action Assessment Protocol (MAAP) tool, aimed at achieving transparency
in how mitigation actions (MA) are designed and how they compare in terms of mitigation value. The long-term goal is to
have the MAAP serve as an internationally accepted system for assessing how MA are robust and ambitious enough to
contribute to achieve the mitigation targets of their relevant jurisdiction, and eventually, the trade potential and
exchangeability of carbon credits. As an expansion of the MAAP tool and due to the fact that many MA that are planned to
contribute to countries Nationally Determined Contributions still are at the design stage, the World Bank is in the process
of developing the MAAP-Design, aimed at assessing MA at design stage. The MAAP-Design will therefore be an important
tool to assess how MA at the design stage are robust and ambitious enough to contribute to the achievement of NDC
goals, and national and regional climate and development strategies. In addition, in spite of numerous available MA
designs, the number of implemented actions falls short of the expected and needed level of implementation. This has
been attributed to a mismatch between the design of MA and expected design standards of international financiers,
leading to a backlog in disbursement of readily available funds. Therefore, the MAAP-Design will also enable practitioners
to compare their MA design with existing good practices, and will allow financiers to access pre-assessed quality MAs.
UDP will review the MAAP-Design and provide suggestions on how the tool can be more attuned to the design phase of
mitigation actions (MAs). The peer review will be based on UDP's extensive knowledge and capacity building support on
mitigation actions (MA) in developing countries. The MAAP tool and MAAP-Design will be piloted in an independent
approach on 20 MAs, both at design and implementation stage. Out of the 20 MA, 5 will be selected for a full assessment
including coordination and site visits with the country's MA representative. This initial product will be used to showcase the
MAAP tool and MAAP-Design's utility through a set of outreach activities based on UDP's extensive network of partner
countries and institutions, and on specific events in coordination with the World Bank. The outreach activities will also
serve as a donor outreach process with the aim to fund future activities to develop and maintain a Mitigation Actions
Database based on MA assessed through the MAAP tool, and to increase the MAAP Tool's application, ease of access
and visibility.

Further, dependent on the donor outreach phase's success, UDP proposes to apply the tool to a selection of 50 MAs.
Lastly, to increase the tool's utility and visibility, UDP proposes to create and maintain a database of MAs assessed with
the MAAP tool and MAAP-Design and make the information publicly available in a user-friendly design on a dedicated
website.

The following specifies how UDP intends to carry out the three tasks described in the Terms of Reference:
1. Support the development of a version of the MAAP Tool aimed at assessing mitigation actions at the design stage.
2. Design and implement an independent assessment process for mitigation actions using the MAAP Tool.
3. Enhance the comparability of mitigation actions by providing the relevant information to different stakeholders in the form
   of a publicly available database.

Systems Analysis  
DTU Climate Centre
Access to shared cars may facilitate living without a private car in the household, fewer private cars can pave the way for more sustainable transport patterns, while better opportunities to choose and combine transport modes may enhance multimodal transport chains.

Several international studies indicate positive environmental effects of car-sharing services but many of these studies are solely based on retrospective data or miss a control group.

Based on a longitudinal survey including both DriveNow users and non-users, the project will
(1) examine the effects of free-floating car-sharing in the Capital Region with regard to car use and ownership and related intentions and attitudes;
(2) monitor the awareness and use of the system; and
(3) examine possibilities for system improvements.
Management of Maritime operations under Emission Control Regulations (MANECO)

Brief summary of project:
Air pollution from ships such as NOx and SOx is currently at the center stage of discussion by the world shipping community and the tools of Operations Research (OR) and Management Science (MS) in reducing the environmental externalities of maritime transport will get increased attention. Therefore education and research in the area of maritime management under emission control regulations are needed. Both the education of engineers in maritime management and research in operations under emission control regulations are addressed in this project. In the research part of this project the focus will be on logistic-based (tactical and operational) measures such as routing, scheduling, and monitoring, however in the educational part other areas of operations may be included such as disruption management, stowage and planning. The project also includes an educational part creating a focus on maritime management which will give students insight into management of maritime operations in order to produce graduates who can not only manage maritime operations of companies, but also improve competitiveness. Development of courses and a project portfolio is needed in order to enhance the student competencies within the area of maritime management. The aim is to create a profile for maritime management to promote courses in maritime management to student and accommodate the industry need for engineers with maritime management skills.

Innovative re-making of markets and business models in a renewable energy system based on wind power

The purpose of the I-REMB project is to assess and develop the technological, market and business options that can support the development of energy systems based predominantly on wind power. The project's aim is to mobilize expertise from renewable energy system engineering, business economics, and economic sociology to generate innovative design solutions to the new technical, regulatory and market contexts of fluctuating energy. For the many actors in the value chain – from generation, distribution to consumption – there are great uncertainties as to how to respond to the unclear commercial opportunities associated with the new variable RES. The conditions for facilitating a successful interaction of the technical and commercial steps towards a successful transition require new design solutions for regulations and market and non-market pricing, as well as an approach to involve existing and new actors in the energy system.

**NSON-DK - North Sea Offshore Network - Denmark**
The focal point of the NSON-DK project is how the future massive offshore wind power and the associated offshore grid development will affect the Danish power system in the transition towards a future sustainable energy system. NSON-DK is a Danish part of the North Sea Offshore and Storage Network (NSON) project framework, which has emerged from the European Energy Research Alliance (EERA) as a pioneer project framework joining nationally funded research according to the European Commission’s Berlin model.
The objective of the NSON-DK project is to study how the future massive offshore wind power and the associated offshore grid development will affect the Danish power system on short term, medium term and long term towards of the transition towards a future sustainable energy system.
The following research questions will have special attention in the project:
- How will the offshore wind power development affect the variability and uncertainty of variable renewable generation in the Danish power system and neighboring systems?
- How will this increased variability and uncertainty from the offshore wind power development together with onshore renewable generation development influence the balancing and need for reserves in the Danish power system?
- How will the offshore wind power and offshore grid development influence the electricity markets in future systems with large scale energy storage and coordination of the electricity system with other energy systems (mainly heat and transport)?
- How will the scale and architecture of the offshore grid development influence the adequacy and security of supply in the Danish power system?
- Which policy instruments should be applied to support an effective and cost-efficient transition of the Danish power system combining the offshore development with energy storage and coordination between energy systems?

PEAKapp - Personal Energy Administration Kiosk application: an ICT-ecosystem for Energy Savings through Behavioural Change, Flexible Tariffs and Fun

Summary
PEAKapp targets the development of an unprecedented ICT-to- Human ecosystem to trigger lasting energy savings through behavioural change and continuous engagement, to enable increased consumption of clean and low-priced electricity from the spot market for household customers, to connect them to social networks, to motivate them through serious gaming, and to boost the efficacy of Smart Home building energy management systems by integrating their functionalities into the PEAKapp solution. With this first close-to-market-ready attempt to provide households with a dynamic electricity tariff in the EU, the door is opened for the most significant impact on the household electricity market since its liberalisation.

The ICT ecosystem will be designed to require smart meters as only hardware with respect to in-house equipment, such that the system can be implemented almost immediately, given the EU targets for smart meter roll-out. These low hardware requirements allow for a fast market uptake, and thus a noticeable impact on EU energy consumption can be experienced with almost no delay and without the need of having to equip the 230 mio dwellings in the EU with any extra efficiency hardware.

Validation of the ICT ecosystem under real life conditions in the publicly owned social housing sector will be carried out in Austria, Estonia, Sweden and Finland, and analyses of the collected data will allow for ground-breaking insights into consumer behaviour, while outstanding EU energy market analyses will derive implications for regulatory practice to better support energy efficiency goals. An outstanding market uptake strategy makes >3 electricity utilities ready-to-sign the implementation of the ICT-system, advises the European social housing sector about its benefits, and fosters European and international market uptake by distinguished exploitation activities, where the leading US stakeholder EPRI takes responsibility without funding.

DTU-MAN Focus
WP4: Customer engagement analysis and savings impact assessment
Task 4.1 Modelling consumer behaviour through econometric time-series analysis (8 mm)
WP5: Market transformation, Privacy and Regulatory Framework
Task 5.2 Market transformation through dynamic electricity prices - assess effects of the market price and distribution costs of electricity from consumer load shifting via PEAKapp (7 mm)
Task 5.3 Regulatory framework (2 mm) - analyse and develop regulatory framework necessary to enable full exploitation of the PEAKapp

Integrated Baltic offshore wind electricity grid development
The offshore wind energy sector in the Baltic Sea requires coordinated transnational grid planning to realise its full growth potential. Project

Smart grid transitions and institutionalizations – market formations and consumers
This project is the Danish contribution to the International Energy Agency smart grid corporation ISGAN, Annex 7.

Smart Grid deployment is seen as a long term endeavour which should be informed by research from multiple disciplinary fields. The general objectives is to: (1) support the development of transition pathways and processes leading to electricity systems with distributed energy resources feeding into distribution grids and (2) to collect knowledge from various studies and make it palpable for policymakers and other stakeholders at multiple administrative levels from and across smart grid related policy fields.

The general Annex 7 activities are led by Senior Researcher Klaus Kubeczko, Austrian Institute of Technology (AIT), Innovation Systems Department. Additional partners are from: Belgium, The Netherlands, Sweden, France, Italy, Canada; and Germany.

The Danish project is made possible through financial support from EUDP.

FutureGas
An effective and economically efficient integration of gas, renewable based gas as well as natural gas, requires three issues to be fulfilled: 1) In an overall system context, gas should be integrated where the system benefits are highest; 2) Gas should be used optimally, that is where the economic net gains are largest taking into account the cost of possible conditioning; and 3) If needed then conditioning of gas should be carried out in the most cost-efficient way. Conditioning here refers to cleaning, upgrading, mixing and/or pressurising to achieve a desired gas quality. Of course, this reflects that the high value areas for gas utilization depend on how gas enters into the energy system. Thus, to find the most efficient and cost-competitive solutions it is crucial in an energy system perspective to address the need, possibilities and cost-effectiveness for conditioning gas to be injected into the gas grids and how different gases most economically and efficiently can be utilized. A central part of this project is therefore to model both renewables injected to the gas grid as well as alternative uses of gas in an overall system context.

The aim of the FutureGas project is twofold:
1) In an energy system context to facilitate the integration of the gas system with the power system, the district heating system and the transportation sector taking into account possible synergies. Despite the huge amounts of energy being transported through the gas grid, it is currently only loosely coupled to the rest of the energy system mainly through use of gas in CHP plants.
2) To facilitate a cost-efficient uptake of renewable gases, hereby in the longer term substituting natural gas and fossil fuels. A number of renewable gases exist, differing in their possible application in the energy system and in their costs and requirements for conditioning. The best and most cost-effective solutions for utilising and conditioning a variety of renewable gases depend on the development of the entire energy system.

In FutureGas these two issues will be looked into with regard to energy system integration, gas conditioning and, finally, economic/policy perspectives. To enable this, a novel modelling framework will be developed comprising the total energy system with an international market dimension and handling risk and uncertainty. Moreover, this new framework will facilitate combined modelling of the physical energy systems with markets and policy instruments. Thus this project has a truly interdisciplinary nature. The major part of the research will be concentrated on addressing the gas supply side on conditioning of RE gases and operation of the gas grid in combination with the demand side (CHP, industry and transport) all in a system context, on developing the gas dimension in advanced system modelling and, finally, on identifying the required policy and market structures for a successful implementation.

Thus the overall vision of FutureGas is to pave the way for an effective and cost-efficient transition to an energy system independent of fossil fuels, ensuring a strong integration of gas with the entire energy system, an economically optimal conversion to renewable gases substituting natural gas in the long run and good access to gas markets for a wide range of gas producing technologies.

Flex4RES - Flexible Nordic Energy Systems
The Flex4RES project investigates how an intensified interaction between coupled energy markets, supported by coherent regulatory frameworks, can facilitate the integration of variable renewable energy (VRE) in turn ensuring stable, sustainable and cost-efficient Nordic energy systems.
The primary objective of Flex4RES is to identify and assess regulatory and technical pathways towards coherent Nordic energy systems in 2050 based on strong interaction between different energy markets that ensure resilience, sustainability and efficiency.

**Flexibility for Variable Renewable Energy Integration in the Nordic Energy Systems**

Flex4RES will assess how to integrate and consolidate different energy markets to make a solid base to anchor resilient, sustainable, cost-efficient and coherent Nordic energy systems in 2050.

Danish energy policy includes ambitious targets for energy savings that are important for reducing CO2-emissions and the dependency of fossil fuels. Large saving potentials exist, however, excluding the properties of energy supply with regard to marginal fuels and marginal capital costs some may lead to socio-economic in-optimal solutions. The project develops methods and models to address both energy saving and energy supply to ensure optimality in investments on both sides simultaneously. Dynamic aspects of costs curves and energy system modelling will be essential.

The research project running 2015-2018, will examine what makes Danish households and companies invest in energy saving solutions.

The objective of the PhD project is to understand key parameters related to energy saving and energy supply. This includes:
- Clarify the value of various types of energy savings linking to the energy supply fuels and technology costs.
- Building a tool to compare saving cost curves with supply cost curves in order to find trade-off between these when reaching certain renewable energy targets or fossil fuel reductions.
- Extending the energy system optimisation model Balmorel, to include energy saving investments and additional end-use sectors.
- Analyse different policy scenarios with the expanded Balmorel model.

Initiative for Climate Action Transparency
The Initiative aims to facilitate effective decision making and policy design, rooted in credible data. The Initiative will provide tools for policymakers and stakeholders to collect more robust and consistent data on emissions, mitigation and adaptation efforts, capacity building and support. Better availability and quality of data will allow for assessment of the impact and effectiveness of domestic climate policies and set in motion an upward spiral of ambition and implementation. In addition to providing the guidance and tools for policy evaluation, the Initiative will create a space for countries to share their experiences and lessons learned.
ICAT is designed to finance activities at the country, regional and global levels to drive immediate and long-term impacts that will result in sustained improvements to the administrative, legislative and institutional transparency infrastructure within countries. The activities will include guidance and other supporting tools, technical assistance, and regional and international networking through peer exchange.

Mitigating and reversing the side-effects of environmental legislation on Ro-Ro shipping in Northern Europe

The main objective of this project is to identify and assess possible technical, operational, regulatory and financial measures for the mitigation and reversal of the negative repercussions of environmental legislation to the market shares of Ro-Ro shipping in Northern Europe. The project builds upon prior research by the Principal Investigator and his colleagues in recent years and will be under the umbrella of Maritime DTU. The project is funded by the Danish Maritime Fund.

Networks between bioenergy and biotechnology - Strategic Research Alliance on Energy Innovation Systems and Their Dynamics

The topic of the sub-project is to investigate the networking between biotech and bioenergy companies and transfer of technology between industries, especially in Denmark, to date. It is well-known that bioenergy in Denmark is often closely connected to the agricultural sector. Compared to this, the connection and interplay with the biotech industry is less illuminated. The connections between the bioenergy sector and biotech industry can be expected to be of high importance for the future competitiveness of new bioenergy solutions as well as wider industrial biotechnology industry both within Denmark and in the global markets. However, there is need of more systematic insight and better understanding of innovation activities and networks between biotech actors and bioenergy actors. The main approach will be network analysis based on data such as joint patents and collaboration in publicly subsidized R&D programs. The purpose of the proposed research is to analyze the Danish energy innovation system its dynamics and development trajectory. The contribution is identification of interaction dynamics between innovation systems and the role of the functions in shaping that co-evolution. These research findings will have implications for RDI and energy policy in addition to the contribution to literature on innovation systems.

Definition of a generic decision making framework and design of an Open Decision Support Platform
The research activity is addressing the definition of the overall decision theoretical and methodical framework to structure and facilitate decision processes when different decision alternatives are available and when the available information are
subject to uncertainty and/or are incomplete, thus providing a robust tool to rank those alternatives in accordance with their consequences on sustainability, benefits and risks. Moreover, the framework shall facilitate the introduction of new information, changes in preferences and models and expert opinions with associated uncertainties. Based on the developed theoretical framework integrating quantitative assessment of risk and sustainability, the architecture of an Open Platform for the storage of information and models, the organisation of an analysis of models as well as the presentation of results of decision analyses shall be developed.

The research activity is part of the joint GDSI project aiming at supporting decision makers from industry and public authorities.

The Adaptation Finance Gap Report
The 2016 Adaptation Gap Report assesses the difference between the financial costs of adapting to climate change in developing countries and the amount of money actually available to meet these costs – a difference known as the “adaptation finance gap”. Like the 2014 report, the 2016 report focuses on developing countries, where adaptation capacity is often the lowest and needs the highest, and concentrates on the period up to 2050.

**Fostering the use of renewable energies for heating and cooling**

The progRESsHEAT project aims at assisting local, regional, national and EU political leaders in developing policy and strategies to ensure a quick and efficient deployment of renewables in heating and cooling networks. The project's aim is in line with the objectives of the Renewable Energy Directive and the Energy Performance of Buildings Directive that require Member States to develop ambitious policies as regards the use of renewable energy sources and energy efficiency in heating and cooling networks. progRESsHEAT is intended to support the market uptake of existing and emerging renewable electricity, heating and cooling technologies. More specifically, the project helps policy makers develop integrated, effective and efficient policy strategies aimed at achieving a fast and strong penetration of renewable and efficient heating and cooling systems. This includes the analysis of cross-sectoral effects between renewables and energy efficiency measures in industrial heat and cold, waste heat, heating and cooling in buildings and district heating. Together with six local authorities in six target countries across Europe (Austria, Germany, Czech Republic, Denmark, Portugal, Romania), heating and cooling strategies will be developed through a profound analysis of (1) heating and cooling demand and future developments, (2) long-term potential of renewable energies and waste heat in the regions, (3) barriers & drivers and (4) a model-based assessment of policy intervention in scenarios up to 2050. The established local energy advisory tool EnergyPRO will be used for the local studies and further developed to appropriately reflect district heating and cooling. The final versions for the investigated regions will be handed over to the authorities. In the target countries, progRESsHEAT will support the implementation of national heating and cooling plans which have to be released by member states by the end of 2015. The plans will include a policy outlook on how the potentials identified by the comprehensive assessment will be achieved. progRESsHEAT will assist national policy makers in implementing suitable policies with a model-based quantitative impact assessment of local, regional and national policies up to 2050. Policy makers and other stakeholders are strongly considered in the process. They will be offered the opportunity to learn from the experience of other players and gain deep understanding of the impact of policy instruments and their specific design. They are involved in the project via policy group meetings, workshops, interviews and webinars dedicated to policy development assistance, capacity-building and dissemination. The project is supported by the Horizon 2020 programme of the European Union.

Sustainable path creation for innovative value chains for organic waste products
The project will address the potential for value added and improved sustainability in the valorisation of organic waste streams, residual feedstock and by-products by analysing value chains inside and across different sectors of the bioeconomy. We will analyse a number of industrial cases from different parts of the bioeconomy and collaborate with highly relevant industry actors and technology experts. The project will help policymakers better govern and regulate the organic waste and residue (OW) industry and the industry actors to identify and exploit new opportunities in the bioeconomy.
The objectives of the project are to:
•Map industrial capabilities and research and human resources in the OW related industries, and consider whether and where policy intervention may be needed.
•Help industrial actors to identify possible pathways to increase their rate of innovation and value added from OW related activities.
•Carry out life cycle assessments and comparative analyses of environmental performance of OW value chains and selected case studies to help government and companies to select environmentally beneficial resources, products and production processes.
•Assess how the regulatory framework influences the management of organic waste streams in Norway and in the other Scandinavian countries and how the governance systems supports innovation, industrial development and sustainability.

Auctions for Renewable Energy Support: Effective use and efficient implementation options
Auctions, as a competitive and market-based mechanism, are on the verge of becoming a prevailing feature in support policies for renewable energy in Europe. A comprehensive assessment of auctions and their suitability for renewable support in Europe is urgently needed to facilitate their successful design and cost-efficient implementation. Auctions have the potential to significantly improve the performance of renewable electricity support in Europe, but there are potential pitfalls and difficulties to be avoided. AURES combines dedicated, detailed and target-oriented analysis of auctions and their interactions with other energy policy mechanisms and markets with capacity building of policy makers and market participants. The project identifies and evaluates suitable auction design options and their effects under different market conditions using tailored theoretical, empirical, experimental, and model-based approaches, and so develops best practices and policy recommendations for future auction design. Building on worldwide experiences with auctions in energy policy and other industries and on close cooperation with ongoing auction implementation cases in Europe, a strong knowledge base will be developed, enabling policy makers and market participants to make informed decisions. This knowledge base will be processed in a flexible policy support tool that provides policy makers with tailor-made information suited to their specific situation and policy preferences. By facilitating an intense and continuous stakeholder dialogue and by establishing a knowledge sharing network via workshops, webinars, bilateral meetings, and expert consultations, the project will serve as capacity building platform. The project consortium consists of eight renowned public institutions and private firms representing seven European countries and includes some of the leading energy policy experts in Europe, with an impressive track record of successful research and coordination projects.

The project is supported by EU Horizon 2020. It is co-ordinated by DTU Management Engineering. There are 8 partners from 7 European countries. Start January 2015, Duration 3 years.

SAVE-E Energy Savings: Closing the Energy Efficiency Gap
Plans to reduce consumption of fossil fuels and hence emissions of CO2 include substitution to renewable energy sources, increased use of electricity and considerable efficiency improvements. Numerous studies have analysed and shown the feasibility of substitution to - and integration of - renewable energy sources. However, further studies have proven the existence of the energy-efficiency gap (EEG) and experience from various support and promotion policies have revealed that the EEG is hard to overcome. On the basis of these findings the aim of this project is to identify relevant factors influencing the EEG and to derive recommendations on how to surmount the EEG. An economic engineering approach is used to identify potentials of efficiency improvements. Based on this, we conduct a comprehensive micro-economic analysis of energy-saving investment behaviour of industries and households, i.e. identifying barriers for adoption and incentive schemes to resolve them. Combining potentials, barriers and incentives, strategies for implementing targeted improvements are developed and the trade-off between efficiency improvements and supply from renewable energy sources analysed. To evaluate macro-economic effects of the investments in savings a small macroeconomic model with detailed energy specifications is developed. Using this model, effects on growth, employment and public finances from using various incentive schemes are quantified.

The objectives of the project are to:
- Identify and quantify technical, economic and social barriers for potential energy savings.
- Analyse implementation strategies, evaluate incentives schemes, and find optimal trade-offs between efficiency improvements and additional renewable energy supply.
- Evaluate macro-economic effects of efficiency improvements and alternative incentive schemes.
- Contribute to development of methods and theory in the intersection of energy systems, behavioural economics, energy economics and stochastic programming areas.

  Project

Green REgion for Alternative fuels for Transport
The GREAT project will make TEN-T Scandinavian-Mediterranean Corridor between Hamburg and Oslo/Stockholm one of the first to meet the EU’s directive for alternative fuels. The project will contribute to the decarbonisation of the transport sector, and therefore has the potential to make the corridor an EU best-practice example on how to meet environmental and climate challenges. The unique combination of regional public authorities and private companies working together creates opportunities for new and dynamic developments.

The project takes a holistic approach to promote all kinds of alternative fuels for road transport. It targets end users in a unique collaboration between the public sector, private providers of alternative fuels and vehicle manufacturers.

The project will highlight the business models of alternative fuels infrastructure to speed up the decarbonisation of road transport.

The overall goal is to reduce fossil emissions by establishing a strongly increased market demand for alternative fuels transport solutions by ensuring access to supply over the long distances between metropolises in northern Europe.
The successful introduction of cleaner transportation solutions on a large scale remains critical to the current European Union goals for reducing reliance on fossil fuels and their effect on the environment.

GREAT is divided into the following activities:

Activity 1: Project Management
Activity 2: Communication and Dissemination
Activity 3: Implementation of pilot infrastructure - E-Mobility
Activity 4: Implementation of pilot infrastructure – LNG
Activity 5: Study – Policy Measures
Activity 6: Study – Business Models
Activity 7: Study – Evaluation, Assessment and Future Development

DTU is leader of Activity 7.

“Ta’ cyklen Danmark” – Effect evaluation
“Go cycling Denmark” is a campaign based project with a variety of promotional activities to encourage Danes to cycle (more). The campaign’s overall objective is to reach a 1% increase in the number of bicycle trips nationwide. Promotional activities include among others an application for smartphones, which is a digital cycling coach that encourages cycling by setting realistic goals, registering cycling trips, and following-up on the goals.

The project runs over three years and will then be evaluated with regard to the effect on cycling (effect evaluation), the impact on health and economy and the process. DTU is responsible for the effect evaluation. The effect evaluation is based on four data sources:

(1)Repeated surveys on the awareness of the campaigns, mobility behaviour and attitudes in a sample of the total population
(2)Data of the cycling app and online questionnaires to app users
(3)Data of the Danish national travel survey
(4)Documentation of all campaign activities (time, regional distribution)

Spatial and temporal variations in the campaign activity will be related to cycling frequency based on the different data sources as a basis for the effect analysis.

Global Opportunities for Danish SMEs in Emerging Markets: Strategies and Methods for Adaptive Product Development
Many Danish companies realise that the growth potential relies on a successful entry into the emerging markets, such as China, Brazil, India, Latin America, and Africa.
There are tremendous amount of opportunities to do business in more innovative ways in emerging markets. Do you face challenges in developing business for your company in emerging markets or adapting your products to these new markets?
The purpose of this project is to accelerate the growth of Danish start-ups and SMEs with regard to their global expansion into emerging markets through establishing new growth strategy and methods to support: understanding of product requirements, product development processes, business models, and pathways for networked resources.
The project is financed with 4.000.000 DKK from the Danish Industry Foundation (Industriens Fond) and runs over a three
year period. It will involve a number of researchers from the Department of DTU Management Engineering.

Risk analysis: hazardous goods and freight train restrictions in the Danish fixed links

The Danish Transport Authority and operators of the Danish fixed links (Øresund, Storebælt and Femern) have requested DTU to assess the risk of freight trains, possibly carrying hazardous goods (i.e. RID-classified goods), using the fixed links in close distance to passenger trains. At present, restrictions are in place, which prohibit freight trains and passenger trains to be in tunnel tubes simultaneously, which leads to a decrease of the transport capacity.

The risk analysis focusses on the risk to passengers in passenger trains due to freight trains being in the tunnels simultaneously, and will not address the risk to disruption of the transport due to damage to the infrastructure, because this is already an accepted risk for freight trains passing the fixed links.

The purpose of the risk assessment is to provide insights into the changes in risk when restrictions for simultaneous presence of freight trains and passenger trains in the same tunnel tube are changed (and where several options are possible) and what safety measures might be beneficial for reducing risks ALARP (As Low As Reasonably Practicable) when restrictions are relaxed.

Assessment of the necessary economic incentives for economic viability of the Hysol technology in the Kingdom of Saudi Arabia, Chile and Mexico.

Innovative Configuration for a Fully Renewable Hybrid CSP Plant

Renewable energies are often criticized for not being able to produce supply power to the electrical grid in a manner that is stable, firm and reliable. This difficulty can find a proper and viable solution through hybrid CSP/biomass plants. The market is showing a strong interest in hybrid technologies for power generation. For instance; the American company eSolar (owned by General Electric) has established an alliance with the Chinese company Penglai, in order to develop CSP/biomass technology, sharing turbines and other infrastructure, reducing costs and producing energy throughout the whole day.

The aim of HYSOL Project is to become the European reference in competition to this and other initiatives ongoing in the CSP/biomass global market. The HYSOL Project focusses on overcoming the CSP technology limitations to increase its contribution in the global electric market, hybridising with biomass energy to achieve 100 % renewable and sustainable energy, and providing a stable and reliable power independently of meteorological circumstances.

GENERAL OBJECTIVE
The main added value of the hybridisation concept will be the achievement of the Europe Strategic Energy Technology plan (SET-Plan), which is the market, the industry and the European Union goal on energy matters: self-producing firm renewable energy with an optimal cost-efficiency ratio.

The present proposal focuses on the study, the design, the pre-industrial scale demonstration of around 2,5MWth and the optimisation of an innovative configuration based on a new HRS (gas-molten salt) and an AGT simulator implemented in an existing CSP plant. In addition, gas fuel used in the AGT simulator will be produced from biomass considering the environmental sustainability factor; therefore, the hybrid installation will become a full renewable plant.

Development of Knowledge Management System on Energy Efficiency
The idea of developing a Knowledge Management System (KMS) on Energy Efficiency is to enable policy makers, energy practitioners and end users to have quick and seamless access to relevant information. The key function of the KMS is to allow the user to search and retrieve useful information based on filtered queries. The purpose of the system is to gather as many points of information as possible regarding energy efficiency and store them in a knowledge database. Then it will provide all the necessary tools for computerized collection and the ability to connect with other databases. End users will obtain relevant insights and ideas appropriate to their work from the KMS through advance searching capabilities. The process will be more effective through the use of tags, which are machine-understandable and so the system can be actively involved in assisting the end user to find relevant information.

One of the primary outcomes of the KMS is to improve the planning for, and follow-up on, energy efficiency initiatives based on information-sharing and dialogue between the energy efficiency community and other stakeholders.
This outcome will be achieved through two activities:
1. Creating a knowledge management system where users can access current information on energy efficiency; and
2. Building knowledge and sharing experiences among the network of organisations and experts involved in energy
efficiency.

The multiple benefits of measures to improve energy efficiency

The study provides world and G20 national- and sector-specific estimates of the emissions reduction potential associated with energy efficiency measures. To this end it relies on two world-class energy-economy models, thus quantifying the uncertainty associated with the estimates.

Model outputs are used in an econometric model, to assess the macro-economic impacts of measures aimed at improving energy efficiency. Assessed impacts include GDP growth, employment and trade balances, among others. For each
country, national aggregates and sector specific figures (each with its uncertainty range) are provided.

The project further includes a survey of national policies in key sectors relevant to energy efficiency, such as iron and steel industry or household appliances, among others. For each sector three-to-five national cases are provided, each outlining measures that have proven effective in improving energy efficiency in that sector. These descriptions contain semi-quantitative assessments of the multiple benefits associated with improving energy efficiency (for example, impacts on human health, public budgets or environmental conditions).

Methods for knowledge transfer from offshore units operating phase to design, planning and operation optimization
This two-year research project aims to 1) develop and test a methodology to capture and transfer operational knowledge and experiences, and 2) integrate these experiences with the existing knowledge transfer systems within the offshore sector. The research questions driving the project are: 1) How operational experiences and knowledge can be captured in a systematic way and reflecting the actual work practices on board offshore units, and 2) How this captured knowledge can be transformed into valuable information and transferred to onshore staff working with design of new units, equipment and optimization of existing units? There is a big difference, both geographical and workwise, between the offshore operators and the onshore staff. This difference reinforces the need for an experience transfer system that overcomes the existing communication barriers. Knowledge from offshore operations can optimize new projects and existing units in terms of costs, safety and production effectiveness. The project is in collaboration with Maersk Drilling and funded by the Danish Maritime Fund. The main outcome will be a validated toolkit with guidelines that can help offshore companies in improving safety, health and production efficiency on board offshore installations.

Success in the face of uncertainty: human resilience and the accident risk bow-tie (SAFERA framework project)
The research addresses success rather than failure and the topics of resilience, improving management of safety and whether resilience concepts can be integrated into classical bow-tie approaches. The Dutch institute RIVM has an interest in scenario-based methods using their bow-tie structured accident analysis tool Storybuilder™. The bow-tie is a linear model with a focus on the negative, the already occurred accidents. Resilience modelling is a mirror of this in being proactive rather than reactive in the face of unanticipated scenarios. The research aims to unite the strong points of both sides, focusing on the mental models of people delivering success in handling uncertainty.

A resilience questionnaire, focused on how people mentally model the changing risk environment, will be developed for interviewing people who have to deal with high risk control problems such as mountain climbing, tactical military training, management of major hazard (petro)chemical installations and dangerous maintenance tasks. The result will be information on the mental characteristics of people that manage high risk environments resiliently, providing inspiring case studies in this regard across sectors, which will help determine what organisations should do to stimulate resilience within their own human capital. Further, the mental modelling work will be incorporated in the publically available Storybuilder™ bow-tie tool. Structural and reliability modelling will be done to see how the bow-tie, a well-known risk management tool, can be improved for incorporating the resilience factor such that qualitative and quantitative bow-tie outputs will encompass the success factor rather than failure. The model will finally be filled with a demonstration set of accident scenarios to show how negative events can be translated into a showcase of positive lessons.

The outcomes will benefit current users of bow-tie modelling by providing lessons learned on resilience which will be offered to sector organisations of participating businesses as well as organised learning opportunities provided through a website, a webinars and a workshop.
DTU will contribute to bow-tie modelling, formalisation of the mental modelling within the framework of bow-tie modelling. Furthermore, DTU will contribute with knowledge and experience of how to optimise the use of research in the practical implementation in industry across all the main processes of the project and by writing the Manual and one of the articles. DTU will assist by providing access to DTU tools/knowledge associated with barrier success modelling.

QUAN-TOX
QUAN-TOX is a four-year project aiming at extending, disseminating, and harmonizing the QUANtification of human and ecosystem TOXicity impacts when assessing the sustainability of products and services over their life cycle. Research will identify and address existing gaps in current toxicity assessment models. Dissemination of research results includes scientific publications and knowledge transfer including teaching activities and elaborating training material. As a result, QUAN-TOX promotes sustainability aspects towards integration into European legislation and strengthens Europe's role in raising scientific awareness of aspects around risk minimization, product optimization, and life cycle thinking, which is in line with the Europe 2020 economy growth strategy. Thereby, QUAN-TOX will play a key role at the interface between researchers in life cycle toxicity assessment and stakeholders including policy makers at the European scale, community organisations, industry, academy, schools and students, and the general public. Finally, QUAN-TOX helps to tackle societal challenges like human health and well-being, sustainable agriculture, and clean energy that all reflect policy priorities according to the Horizon 2020 EU Framework Programme for Research and Innovation.

Methods for employee participation in product innovation

The aim of the two year project is to develop and test methods for planning and executing product innovation by involving employees from the manufacturing process. The development of new products is often confined to the knowledge of engineers and specialist in the R&D department, while ideas and knowledge from the manufacturing process only to a limited extent is applied in product innovation. The methods developed in this project contribute to foster collaboration between manufacturing and product development departments, so ideas and knowledge from manufacturing naturally are included in and strengthen product innovation. Three large and medium sized companies are involved in the project to test the developed methods. A training program is developed and offered to interested companies in the end of the project period to disseminate the methods for wider use in industry.

Consultancy Support for Energy and Greenhouse Gas Analyses for the Danish Energy Agency

Higher energy efficiency and increased deployment and integration of renewable energy are key mitigation strategies for reducing anthropogenic greenhouse gas emissions and thus combating climate change. Developing economies constitute a particular challenge in this regard, often lacking the technological development or the financial resources to invest in a greater share of renewable energy within the context of sustainable development. Within the last decade, industrial greenhouse gas emission from the non-Annex B Kyoto countries surpassed those of the Annex B (Boden et al., 2013). In light of this, developed counties, such as Denmark, have the opportunity to lend their expertise to developing regions of the world in order to promote sustainable development through energy efficiency and renewable energy development. Part of this process involves identification of opportunities for renewable energy expansion and energy efficiency.
improvements, under the framework of integrated assessment of mitigation instruments. Herein, we describe a model-based approach for integrated assessment that takes into account both developed and developing regions of the world within the global context. Integrated Assessment models were designed to identify the least expensive mitigation options. The linkage between energy, economics, and the environment within the integrated assessment framework provides a tool that leads to better understanding of how to most optimally meet specific energy, environmental, or climate constraints. Included in integrated assessment models are mitigation potentials for each global region and sector, costs, different technology penetration levels and efficiency improvements and their effect on climate mitigation, and comparison of different policy and regulatory instruments.

Project

Green Climate Fund Readiness (Ghana & Benin)
The Green Climate Fund Readiness Programme builds countries’ capacity to access the Green Climate Fund, through preparing countries to plan for, manage, disburse and monitor climate financing.
By offering results-oriented support, the Programme helps strengthen national climate finance institutional frameworks, assist in identifying climate change activities with high funding priority for the countries, and facilitate increased investment of the private sector in climate relevant areas.

**Nordic Built Campus Retrofit - CARE**
Nordic Built Campus retrofit (CARE) targets to improve cooperation among businesses in the Nordic building sector by testing co-creative and innovative retrofit concepts and processes in Nordic campuses. The showcases with measured evidence of energy- and user-effectiveness are reported in forms of strategic guidelines, tactical use and design manuals and criteria for retrofit business. The outcomes can be applied both in campuses and urban areas in development work and in providing service.

Green Cohesive Agricultural Resource Management
The project wants to promote growth and employment through research on green, cohesive Water, Energy-from-Biomass, Soil, Organics, and Crop (WEBSOC) agricultural management strategies in Ghana, as present agricultural development depends on deforestation and show little or no increase in productivity per unit of land. WEBSOC is intended to intensify agriculture to create jobs in poor rural areas. The project will investigate the use of crop residues to produce biochar and wood gas for household-use to lessen the pressure on forests for firewood and charcoal as an intelligent way of recycling organics and reducing CO2 emission. The application of biochar to agricultural fields increases carbon sequestration into the soil and thereby represents a CO2-negative approach to sustainable increase soil fertility, crop yields, and carbon storage. Further intensification will be achieved by small-scale solar drip fertigation systems allowing one to two more growing seasons per year to produce high-value horticultural crops. This is a triple-win situation where farmers get sustained higher yields (from irrigation and improved soil fertility), CC gas emissions are reduced (from increased carbon sequestration), and households get energy (from pyrolysis of straw). Finally, agricultural value chains, both on the supply and processing side, will be developed in cooperation between local SMEs and universities. The research into these options will be pursued within a framework designed to educate PhD students and young scientists.

Supported by the Danida Fellowship Centre.
Department of Management Engineering
Center for IT-Intelligent Energy Systems for Cities

A wide range of research activities have arisen to support the Danish target of a 100% renewable energy system by 2050. Projects focused on individual aspects of the energy system, such as zero emissions buildings or intelligent power systems provide valuable insight, that facilitates flexibility throughout the energy system. CITIES will address this deficiency by establishing an integrated research centre covering all aspects of the energy system, including gas, power, district heating/cooling and biomass, and most importantly methods to forecast, control and optimize their interactions through the use of advanced ICT solutions.

The high densities of population, energy consumption, and energy and communications networks in cities offer the greatest potential for flexibility at the last cost, and the fact that cities account for 80% of global energy consumption and emissions [1] make the urban environment an ideal setting for energy systems integration research. CITIES will pioneer research into fully integrated city energy systems, building short-term operational models that feed longer term planning models, considering the spatiotemporal variations, interactions, dynamics and stochastics in the energy system. Low level models of system components will inform higher-level aggregate models employed in market and control framework design. The leading position of European academia and industry and the rapidly growing market for smart energy solutions indicates substantial scope for increased competitiveness and job creation within this field. CITIES will, in collaboration with its industrial and academic partners, conduct research with a view to developing tools for the implementation of integrated energy system solutions.

**From BACterial Hosts for production of Bioactive phenolics from bERRY fruits to products**

In the era of increased environmental and health awareness, new ways are being explored to fully exploit to this day unrivalled natural resources with renewable bio-production. These new production methods will generate a sustainable pipeline of environmentally-friendly methods to enable production of pharma and agrochemical products with bioactive properties from berry fruits.

This project stands out in bringing together the most recent technologies within the framework of systems metabolic engineering to develop the next-generation bacterial cell factories for the production of plant phenolics, and in applying it to phenolic compounds from cultivated, wild, and underutilized species of berries - recognized for their antioxidant, health-promoting and functional properties and applied across applications as diverse as aromas, colours, nutraceuticals and medicines.

BacHBERRY (From BACterial Hosts for production of Bioactive phenolics from bERRY fruits to products) sets out over a three-year period to develop a portfolio of sustainable methodologies to mine the potential of the untapped biodiversity of the bioactive phenolic compounds in an extensive collection of berry species. Full exploitation of this unrivalled natural resource requires an integrated and comprehensive effort from bioprospecting in berries using SMART high-throughput screens for the valorisation of phenolic bioactivities aligned with their identification using cutting edge analytics and subsequent elucidation of their biosynthetic pathways. This knowledge will facilitate metabolic engineering of suitable bacterial hosts for high-value phenolics production in scalable fermentation bioprocesses, ultimately serving as commercial production platforms.

**European Clusters for Offshore Wind Servicing**

ECOWindS’ objective is to pave the way for new research and knowledge of how the costs of offshore wind energy can be driven down through better services. The objective is reached by establishing cross-regional cooperation, intensifying the relationship between research, the European offshore wind servicing (OWS) sector and the offshore wind industry. The actions in the project include mapping of regional capabilities, search of RDI projects and building a Joint Action Plan for
regional and international co-operation. ECOWindS is funded from the EU FP7.

Development of 2nd Generation Biorefineries Production of Dicarboxylic Acids and Bio-based Polymers Derived Thereof

The existing 2nd generation biorefineries utilize less than 20% of the biomass feedstock for ethanol production, and major side-streams are produced such as pentose and lignin waste streams, that are respectively used for biogas and energy production.

Converting the carbon from these waste streams into added-value products would increase the otherwise low profitability and improve the environmental benefits of the biorefineries. The suggested project BioREFINE-2G aims at developing commercially attractive processes for efficient conversion of pentose-rich side-streams from biorefineries into dicarboxylic acids, which can be used as precursors for bio-based polymers including biodegradable polymers. The project covers the whole value chain, from characterization of side streams from forest and other non-food feedstock, development of novel robust industrial yeast cell factories, fermentation and downstream process development, to polymerization methods development for the production of biodegradable polymers applicable as plastics, coatings or adhesives, scale-up and demonstration and to life cycle and economic viability analyses.

PLEAN - A Lean method to assess the psychosocial work environment

Improvements of the psycho social working environment are commonly initiated in workplaces based on results from employee questionnaires. The results from the questionnaires should address the possible solutions and programs following the pinpointed problems. However, more frequently the members of the workplace cannot draw these kinds of conclusions about actions from the information gathered in questionnaire, but are left with the problem areas and, without the knowledge of the impact of the problems and coherent solutions.

This interventions project aims at developing a work environment assessment tool based on the workflow analysis in Lean. The close connection between the description and analysis of the flow of task and the assessment of the experienced psycho social work environment suggests improvements closed connected to conducting the core task. In this view, improved psychosocial work environment is closely linked to high performance and the coordination around performing the core task.

The tool is to be developed and tested in 6 hospital wards.

REseach network for forward looking activities and assessment of research and innovation prospects in the fields of Climate, Resource Efficiency and raw mATErials
The overall objective is to support the development of the European Union’s new research funding program Horizon 2020, with a specific focus on "Challenge 5: Climate Action, Resource Efficiency and Raw Materials”. RECREATE will provide evidence and intelligence concerning the future directions of these research fields. RECREATE will run until mid 2018 and is carried out by a consortium of 15 key stakeholders from European research and industry.

Hybridisation of CSP with other energy sources

Renewable energies are often criticized for not being able to produce supply power to the electrical grid in a manner that is stable, firm and reliable. This difficulty can find a proper and viable solution through hybrid CSP/biomass plants. The market is showing a strong interest in hybrid technologies for power generation. The aim of HYSOL Project is to become the European reference in competition to this and other initiatives ongoing in the CSP/biomass global market. The HYSOL Project focuses on overcoming the CSP technology limitations to increase its contribution in the global electric market, hybridising with biomass energy to achieve 100% renewable and sustainable energy, and providing a stable and reliable power independently of meteorological circumstances.

**ConCoord**
The project focuses on the important area of city logistics. It investigates an integrated urban freight simulation environment, a unique measurement framework for the environmental footprint of transport and logistics, and the performance measurement of new innovative urban transport and logistics concepts. Specifically dealing with the different and important considerations of new transportation solutions, new mechanisms for execution and control of city logistics, and research on the urban distribution of goods reducing urban freight movements and its impact on residents and the environment.

The fundamental idea is to stop considering each shipment, actor (e.g. shippers, Logistics Service Providers, etc.) and vehicle in isolation, but as components of an integrated logistics system to be optimized. The keywords are CONsolidation and COORDination (CONCOORD) of the urban distribution flows that are currently fragmented. CONCOORD involves key players in the urban transportation field, both from leading European universities and world-class Europe-based companies, who have expertise and experience in city distribution and who have the willingness to explore this issue for the benefit of all those in Europe.

OPHRA - Offshore Platform Hydrocarbon Risk Analysis – Feasibility study

The purpose of the project is to demonstrate the feasibility of developing a tool to assess the risk on offshore platforms due to releases of hydrocarbons. This risk is to be understood as the risk to personnel, expressed in terms of Individual Fatality Risk (IR), Potential Loss of Life (PLL), Fatal Accident Rate (FAR, at platform and workplace level), and group risk (distribution of number of simultaneous fatalities).

The tool will be based on simulation of the interaction between concurrent phenomena following loss of containment, specifically:
- The physical processes (outflow, dispersion, ignition, heat radiation, explosion)
- Detection, alarming and emergency shutdown
- Escape and evacuation
- Impact on persons, escalation and impairment of safety functions

The interaction between these event trees depend on the stochastic outcome of times needed from one event to the other, this set of event trees will be referred to as the dynamic event trees. The simulation technique will be based on Discrete Event Simulation.

The tool will provide an overall framework to describe and simulate the interactions between the above mentioned concurrent chains of events. The final tool is intended to offer a platform for offshore QRA offering flexibility in choosing data and models to describe these single events.

Focus will be on the documentation of the input that users will use to apply the tool, i.e. the data and models to describe the events in the simulation. The QRA process is considered as combining two sets of knowledge:
1) Assumptions – this consists of the majority of the input to the QRA, such as failure data of components, consequence models, expected responses from systems and people, ambient conditions, the interaction between physical lay-out and impacts, and many other simplifications of reality;
2) Probabilistic reasoning – this consists of the logic reasoning that generates all possible combinations of events in the dynamic event trees according to the assumptions – into final outcomes.

In principle the probabilistic reasoning will include some level of assumption (viz. a limited number of events in the dynamic event trees), but the ideas is that the principle of the probabilistic reasoning can be justified and verified (i.e. it is possible to ensure that a set of input correctly leads to some output) independent of the correctness of the assumptions, so this part can be verified “once and for all”, while the other input, the assumptions, is presented completely and transparently, so that these assumptions can be verified or justified for each study (or consequence models can be verified or validated independently).

The feasibility study will include the following activities:

Generic event trees will be developed for the 4 concurrent processes, and links defined between these processes. The event trees will be expressed with “time from release” as the independent variable. The development of the processes will all be expressed with reference to this time.

Rules for input and documentation

Formal requirements for initial data (information on the platform layout, modules, escape routes, etc.) and the deterministic (for describing physical effects) and stochastic (for describing random events) models contained in the “event boxes” will be established, i.e. dependent parameters and the output of each model will be defined. For example, the model for “jet flame” will depend on release rate, hole size, direction, and deliver as output: flame size, location and radiation contour. Input can be provided either by on-line models, which, for the sake of creating statistical significant results, need to be very simple, or off-line data, such as results from CFD explosion modeling, which requires some processing and interpolation of results in order to transfer results from few scenarios into the DES model.

An important consideration will be to develop criteria or a format for documentation of the assumptions with respect to
completeness, transparency and traceability. For the feasibility study, very simple models for the events will be selected, mainly based on the “Yellow Book” or other similar, relevant sources. Only models necessary to create sufficient credibility of the feasibility study will be included, which e.g. means that the easiest type of release (single phase gas release) will be included.

DTU will deliver to the project partners by the end of the feasibility study:

• A proposal for transparent and complete documentation of QRA assumptions (input), to be delivered by means of a technical report describing structure, and examplification using the demo case study;
• A description of a framework for a QRA technique based on concurrent (dynamic) event trees, evaluated using Discrete Event Simulation, to be delivered by means of a technical report;
• A demonstration of that framework with a simple set of models and data, to be delivered as a workshop demonstration and output by means of screen dumps with explanatory text.

NAMA Partnership Working Group on Sustainable Development
The international partnership on NAMAs has been created with the objective to enhance collaboration and complementarity of the activities of multilateral, bilateral and other organizations to accelerate support to developing countries in preparation and implementation of their NAMAs. The partnership aims to identify best practices and share knowledge to facilitate the preparation and implementation of NAMAs in developing countries, among others.

In support of NAMAs in the context of national sustainable development, a number of activities are proposed under each of the three focus areas identified by the Partnership:

1) Contribution of NAMAs in meeting defined national mitigation goals and targets:
   Develop methodologies (e.g. Excel sheets) for calculating how NAMAs contribute to national mitigation goals and targets and at what cost. Train government officials how to use the methodologies, on demand.

2) Contribution of NAMAs to sustainable development and other national development goals:
   Develop an assessment tool to highlight the SD co-benefits and risks of negative impacts of NAMAs. Train government officials and relevant stakeholders how to use the tool, on demand.

3) Institutional arrangements for NAMAs:
   Develop generic models for institutional frameworks to approve and implement NAMAs. Explore best practice case studies on governance of NAMAs. Organize global/regional platforms to share knowledge and experiences with institutional models for NAMAs.

There is no agreed date to finalize the NAMA Partnership. On the contrary the idea is to keep it active as long as needed

Sustainable Technical and Economic Pathways for Electrified Mobility Systems in EU27 by 2030
The project is part of ERA-NET Plus Electromobility+

Pure and Plug-in-Hybrid electric vehicles can provide an appropriate technological answer to EU's energy and environmental strategic goals. They can reduce oil dependency; increase flexibility since many energy carriers can be converted to electricity; increase end-use energy efficiency through the higher efficiency of electric drive train; and significantly reduce transport related greenhouse gases and air pollutants.

But, to avoid a carbon or efficiency leakage from the end-use to the energy supply level, assessments must be performed in an inclusive framework. Building such a framework is complex due to the technological dimension in which the transport system interacts with a highly diverse mobility demand, and with the electric system and energy system more largely.

Introducing a long term prospective dimension and the possible transformation of those interrelated systems increases the complexity of the task. By expanding existing system analysis tools, the EV-STEP project will develop a framework for such an integrated assessment in order to assess the key technical and economic conditions of an increased electrification of European transport systems while covering the spatial heterogeneity of its territory.

The methodology will be implemented by an experienced team of modellers in a common and shared analysis associating a bottom-up energy systems optimization model to a static computable general equilibrium model. The MARKAL/TIMES and IMACLIM-S modelling frameworks will be used. EV-STEP's ultimate goal is to state integrated policy recommendations, evaluate technical roadmaps such as those proposed by the Green Car Initiative and quantify implications for the interconnected European electric and energy system, while determining impacts on EU27's economic input-output balance.
National Transport Planning - sustainability, institutions, tools
A widespread consensus exists internationally and in Denmark about the relevance of pursuing goals for sustainable transport development but only limited research about how national transportation planning can become a pillar in this process. The goal of SUSTAIN is to expand this research and consolidate a framework on three core domains for a National Sustainable Transport Planning (NSTP): 1) sustainability, 2) institutions and 3) tools. Research within these three domains will address the following questions: How can the concept of sustainability be operationalised and transformed into strategic performance measures for national transport planning? How can these types of knowledge about organisational forms and planning processes contribute to the achievement of such sustainability measures? And how can these new types of knowledge be built into new model-based planning tools that can help advance the strategic planning in the desired sustainable direction?
An important feature of SUSTAIN is that it will seek to combine the results of social and technical sciences in planning research with extensive policy relevant knowledge in dialogue with practitioners and international experts. Furthermore, the SUSTAIN research will be underpinned by multi-faceted case research based on both Danish and international cases. Close connection with ongoing Danish planning practice will serve to demonstrate the potential of the formulated NSTP framework, which is expected to have a broad strategic and policy-oriented appeal and impact on promoting future sustainable transport.

GGGI, in partnership with the UAE Ministry of Foreign Affairs, will develop a comprehensive and coherent national Green Growth Plan (GGP) for the UAE over the period of three years (2011-2014). Among the three components of the project – development of a national Green Growth Plan for the UAE, establishment of a national GHG inventory, and capacity building – URC is expected to develop the UAE-tailored capacity building/training programs for policy makers, public officials and stakeholders. Capacity building will mainly involve knowledge-sharing and dissemination through policy dialogues, training programs, workshops and various specialized programs. These programs should be designed and implemented in a way that can best assist the local actors. The objective of the overall capacity building programs is to build the UAE’s own capacity to conduct and refine green growth analysis as well as to translate it into policy decisions and implementation plans that are well aligned with the country’s broader economic, social and environmental interests.

Out of the total project period, this contract is intended for the Phase I (December 2011 - December 2012) activities, where URC is expected to design and organize training programs and policy dialogues as required in the development of the UAE National Strategy for Green Growth and delivery/communication of it with the objectives of:

1) Establishing sectoral programs for policy design and analysis
2) Facilitating the articulation of comprehensive national strategy
3) Organizing sectoral stakeholder workshops February 2012 to December 2012

URC’s main focus will be to design and implement capacity building sessions for sectoral stakeholders from Oil & Gas, Water & Electricity, Transport, Building, Industry and Waste sectors, by organizing specialized sectoral capacity building sessions where each of the six sectors participate at least twice in 2012.

The contract expired end of October 2013. An amendment to extend the contract has been underway since then, awaiting that UAE Government and GGGI could decide on dates for the 2nd knowledge sharing workshops. However, as it has not been possible to confirm dates for the 2nd round of workshops it was agreed the contract will be terminated during February/March 2014.
Modular multi-Use deep water offshore platform harnessing and servicing Mediterranean, subtropical and tropical marine and maritime resources. Deliverable 5.6 – the Viability Strategy.

TROPOS is a European collaborative project funded by the European Commission under the 7th Framework Programme for Research and Development, more specifically under the “Ocean of Tomorrow” call OCEAN 2011.1 – Multi-use offshore platforms. The TROPOS Project aims at developing a floating modular multi-use platform system for use in deep waters, with an initial geographic focus on the Mediterranean, Tropical and Sub-Tropical regions, but designed to be flexible enough so as to not be limited in geographic scope.

TROPOS gathers 20 partners from 9 countries (Spain, the United Kingdom, Germany, Portugal, France, Norway, Denmark, Greece and Taiwan), under the coordination of PLOCAN (Spain - http://www.plocan.eu/es/). The Deliverable 5.6 – the Viability Strategy with the purpose to analyze the integration of the different TEAL service modules (Transport, Energy, Aquaculture, and Leisure) in order to identify the synergies and commonalities arising in the whole system.

Considering earlier deliverables of the TROPOS project (D5.2 - An assessment of the economic impact on local and regional economies of the large scale development, D5.3 - Technology pricing of multiuse marine platforms, D5.4 - Lifecycle assessment of multiuse marine platforms, D5.5 - Supporting infrastructure, supply chains and logistics for the deployment of multiuse marine platforms, D6.1 - Report describing a framework for the environmental and socioeconomic study and D6.2 - Report on environmental impact assessment and mitigation strategies), the viability of the three ICS concepts, Leisure Island, Green and Blue and Sustainable Service Hub, is assessed based on hard infrastructure such as ports and vessels, soft infrastructure such as legislation and personnel and training, the private economic viability, the macroeconomic impacts and environmental effects. The analysis have resulted in a list of recommendations to ensure the viability of the three TROPOS ICS concepts with respect to hard infrastructure and soft infrastructure including environmental aspects and finance.

Modular Multi-use Deep Water Offshore Platform Harnessing and Servicing Mediterranean, Subtropical and Tropical Marine and Maritime Resources

Developing a floating modular multi-use platform system for use in deep waters, with an initial geographic focus on the Mediterranean, Tropical and Sub-Tropical regions. Thanks to its different modules, the floating platform system will be able to integrate a wide range of possible sectors: ocean renewable energy and food (aquaculture) resources will be exploited, the platform will serve as a hub for maritime transport and innovations in the leisure sector, and will also fulfil functions for oceanic observation activities.

Green Corridor in the North Sea Region

GreCOR – Green Corridor in the North Sea Region – is an Interreg IVB North Sea Region project that started the 1st of January 2012. GreCOR will promote the development of a co-modal transport corridor in the North Sea Region. Important in this collaborative approach, is the focus on secondary networks and the hubs, and the regional hinterland around the Green transport corridor Oslo-Randstad from a co-modal perspective.

GreCOR has 14 partners and a total budget of 3.7 M€. It started the 1 January 2012 and will be finalized 31 December 2014. The Swedish Transport Administration is the responsible lead partner for GreCOR.

GreCOR works in close collaboration with public and private stakeholders, and its overall aim is to improve knowledge about the logistic needs and conditions and develop and implement the first green corridor in the North Sea Region in a strategic policy setting.

The main idea of the project is to influence the green corridor consisting of infrastructure and transport development in the area. Furthermore, GreCOR aims to:

- Improve knowledge about the logistics needs and conditions in the corridor
- Test innovative logistics solutions through the development of pilot projects
- Promote the development of sustainable transport in the North Sea Region
- Focus on the role of the hubs and the regional hinterland
- Understand and develop the logistics utility creation in a green corridor taking a co-modal perspective.
- One very important tool for reaching the goals of corridor development is a liaison group to which we invite all relevant organizations, stakeholders and companies to join.

Technological and Market Options for Managing Climate Change Induced Risks for Smallholder Farmers in Northern Ghana

Climate change is likely to affect (and is affecting) the livelihoods of smallholder farmers in many parts of Africa in a negative direction. African smallholders are particularly vulnerable to adverse changes in agro-climatic conditions due to low technological and economic capabilities and an unfavourable institutional and economic environment. This study aims to identify and analyse technological, institutional and policy strategies that can increase the capability of smallholders in northern Ghana to manage climate-change induced risks threatening their livelihoods, thereby reducing vulnerability. This will be achieved through analysing the impacts of climate change on cereal-based farming systems and food markets in northern Ghana. Biophysical and economic models will be developed and used to evaluate the trade-offs and effects of technological and market changes or innovations on farm household resource use, agro-ecosystem sustainability, and household welfare. The results will be used to suggest measures and policies to enhance adaptive capacity and mitigate the negative impacts of climate change.

This project is supported by the Danida Fellowship Centre.

Department of Management Engineering
Biofuel Production from Lignocellulosic Materials

The overall objective of the 2GBIONRG project is to develop sustainable technologies for production of 2nd generation biofuels (biogas, bioethanol and biodiesel) from lignocellulosic waste material in developing countries in Africa. In addition it is also to utilize residuals from the production as fertilizer improving soil fertility and food security. The suggested technologies will make it possible to switch from a society depending more and more on fossil energy to a modern biomass based society. Ghana will be used as a model country. We will develop and adopt sustainable biofuel production systems for three different types of communities: rural villages, cooperatives and large towns.

The project is supported by the Danida Fellowship Centre.

Consequences of large scale bioenergy production in Denmark on biodiversity, forestry, and agriculture in the context of sustainable development

Danish participation in IEA-ETSAP, Annex XII, 2011-2013

The project will continue the Danish participation in the IEA Implementing Agreement ETSAP (Energy Technology Systems Analysis Programme), Annexes X and XI under the new Annex XII 'Policy Analysis Tools for Global Sustainability (PAT-SUS): E4 systems tools and joint studies'. The main activities are semi-annual workshops focusing on model analyses, and use of the ETSAP modelling tools and technology data (the MARKAL/TIMES family of models), participation in training sessions on ETSAP tools, and participation in collaborative projects using and improving the ETSAP tools. Contributions to the workshops are based on past, present and future collaborative projects, in particular within the EU research programmes and projects under the Danish Strategic Research Council. Dissemination of results of ETSAP activities will be made through participation in workshops arranged within the Danish modelling community and as Pre-Conference meetings before ETSAP meetings. The project aims at enabling Danish model studies, which are consistent with European and global models. A TIMES model for Denmark was developed within EU research projects as a part of the Pan European TIMES model, which now covers 36 European countries, using harmonised assumptions based on Eurostat data, and with results that are becoming available online (PET36). Another development within ETSAP is the TIMES Integrated Assessment Model (TIAM), which is a global model covering 15 or 16 regions and time horizon year 2100

Project
To meet 2050 energy and climate policy goals, a major transition is required in the Nordic region. Indeed, changing energy and transport systems may require fundamental social changes. Industrial actors and policy makers will need insights and analyses to help guide their decision-making throughout this process; and, these analyses will have to take account of concerns of environmental sustainability and economic competitiveness.

The TOP-NEST project has developed an approach that addresses this challenge, by clarifying the current situation, and identifying the most promising pathways for towards more sustainable systems.

TOX-TRAIN 
TOX-TRAIN is a 4-year project and its main objective is the development and implementation of a tool box to assess toxicological impacts related to the life-cycle of technologies. The USEtox model, developed under UNEP-SETAC auspices with contributions of the partners in this consortium, will be taken as a starting point. First, TOX-TRAIN will develop and implement estimation tools for emissions and chemical properties to USEtox for a number of compound groups, including ionic and amphiphilic substances, persistent bioaccumulating chemicals or metabolites, pesticides and biocides, substituted musks/fragrances, and metals, with a specific focus on assessing various types of uncertainty in emissions and properties. The compound groups are selected on the basis of use volumes, fate pattern complexity and main emission route relevance. The tools will be developed as open-source software. Second, the USEtox model will be extended with an indoor compartment model for typical exposure situations in working place and household settings as well as direct consumer exposure through a product (e.g. a directly applied cosmetic product). Third, a number of case studies will be performed in close collaboration between the commercial and non-commercial partners of TOX-TRAIN to test the USEtox tool box in practice. Finally, dissemination of the tool box will be done by a portfolio of actions, such as workshops, course developments, training of specific user groups, documentation material, and a user-friendly web-based implementation. In short, TOX-TRAIN will provide an excellent platform to enhance the transfer of knowledge between the commercial and non-commercial sector in the area of toxic life-cycle impact assessment of technologies. It is envisaged that the developed USEtox tool box has a great market potential as it can be directly used in the daily practice of life cycle assessment studies.

Measuring corporate sustainability: models, methods and findings
In recent decades there has been increasing attention to the social and environmental impacts of business. Stakeholders are ever more concerned and responsible about environmental and social issues and prefer to deal with companies that act sustainably. Accordingly, companies are called to continuously communicate with stakeholders about their corporate social responsibility (CSR), in order to improve stakeholder perceptions and meet their expectations. In this dissertation, I focus on the measurement of corporate sustainability, providing new methods for assessing, monitoring and improving corporate sustainability performance. These methods are mainly based on CSR reporting and stakeholder CSR perceptions and expectations. This dissertation contains four articles, three of which propose and apply new models and methods for measuring corporate sustainability performance. In particular, one provides a two-dimensional CSR model for measuring the development of CSR programs and the CSR commitment disclosed by the company. The other two articles provide a method to compare company disclosed CSR commitment with stakeholder CSR perceptions and expectations, and a model to classify customers according to these comparisons. The last article of this dissertation explores the impact of individual characteristics (gender, education and age) on CSR perceptions and expectations.

Road safety in the ageing societies - CONcerns and SOLutions
During the years following the Commission’s first White Paper on a common transport policy, personal mobility has increased and is now seen as an acquired right. It is an ethical and economic necessity that future transport policies be designed to be inclusive, so that all segments of the ageing European populations can be safely mobile and lead autonomous lives as long as possible. CONSOL aims at advancing knowledge by combining current knowledge on mobility and safety with newest evidence from basic research, e.g., gender studies, social gerontology and findings on health and functionality with age, while also covering some less well-known elderly safety issues such as single-pedestrian and non-crash public transport accidents. Best practices will be discussed and recommendations given in a feasibility perspective, analysing the roles of the different societal actors in making things happen.

Technology Opportunities in Nordic energy System Transitions

If Nordic energy and transport systems are to meet the 2050 energy and climate policy goals, a major transition is necessary. Fulfilling these goals may require fundamental social changes, perhaps reminiscent of an industrial revolution. Therefore industry and policymakers need insights and analyses that will help guide decision-making, avoid detrimental consequences and develop viable system transition strategies. This project explores how three renewable energy technology platforms: 1) electricity systems, 2) liquid and gaseous biofuels, and 3) hydrogen systems, may give rise to new value chains, creating entrepreneurial opportunities.

Global Product Development
Most Danish companies have globalised a large part of their development process; from idea generation to
implementation. This has created many new possibilities but also new challenges. Researchers at DTU Management
engineering are working on creating a guide to Danish companies regarding 'best practice' within global product
development. The project is sponsored by the Danish Industry Fond (Industriens Fond).

Department of Management Engineering
Implementation of Environmental Improvements through Product Development

This project focuses on aiding companies in the actual implementation of ecodesign, through best practice case studies and guidelines. It is a continuation of the earlier "MPU" project.

Project

PhD
Project background:

Regulation of chemical substances is traditionally based on knowledge of exposure and effects of each substance separately. This requires that one knows how much we humans are exposed to of each compound, as well as the effects of each of compound.

For the last twenty years insufficient knowledge about cocktail effects (the effects that can occur when substances are found together) and the absence of reliable tools for risk assessment of chemical mixtures has been a source of concern, both in regards to regulation of chemicals, but also concerning development of products and productions methods. The concern has been that the traditional approach to risk assess one substance at a time does not take into account the effects that can occur when substances are found together (cocktail effects).

This concern has led to funding of a 4-year research project, the Cocktail project, supported by the Danish Veterinary and Food Administration (DVFA)

Focus cocktail project:
The focus of the project is the risk of combinations of endocrine disruptors, and the aim of the project is to provide new practical knowledge on combination effects including effects of each substance and for public exposure to these substances.

The primary objectives are:
Specific recommendations for risk assessment of mixtures of substances including:
- 5-year overview of the Danish population's exposure to food chemical contaminants
- Knowledge building on combination effects of chemicals
- Knowledge building in modeling of the combination effects and exposure
- Develop strategy for evaluation of food contact materials
- New potential endocrine disruptors and development of methods to find them
- New technologies to elucidate the effect of chemicals mechanisms such as metabolomics and bioinformatics

The aim is primarily to develop tools for the assessment of combination effects that can actually be used by the DVFA in the risk assessment of chemicals. Currently, these tools are generally non-existent, even at international level, and must be developed from scratch. This means in a broader perspective, that the goal is to build knowledge, develop methods and establish a strong Danish platform at international level in food chemistry and toxicology, which provides the basis for future preparedness in food chemical safety.

The project includes 7 'work packages', each of which focuses on exposure and/or effects and/or risk assessment:
- WP 1 and 2 focuses on experimental work with the aim of generating data and knowledge on toxicological effects.
- WP 3 aims to develop mathematical models, which can be used as in a practical tool for in risk assessment of combinations/mixtures developed in WP 7

Exposure to food contaminants is included in the experimental plan in WP 4 and 6, and a practical approach for the assessment of new food contact materials will be developed in WP 5.

In WP 5 and WP 6 the studies will address toxicological effects of new potential problem substances (e.g. substances in food contact materials and mycotoxins in crops).

GreenShipping - Green Ship Routing and Scheduling

Christos A. Kontovas has recently been awarded a highly competitive Marie Curie Career Integration Grant (FP7-PEOPLE-2013-CIG) by the European Commission within the Seventh Framework Programme (FP7). The grant will support execution of a 2-year project on Green Maritime Logistics.

The project’s main innovation is attributed to the synthesis of its two main pillars, (a) maritime logistics research (especially related to ship outing and scheduling problems) and (b) emissions-related research. This is an area of paramount importance for international shipping and will be even more so in the future. The proposed research would enhance the state of the art in this area by investigating possible reformulations of existing models so as to incorporate emissions considerations and by developing new models altogether that explicitly include the emissions dimension.

A key aspect of the project concerns the link of the logistics/emissions research to the relative regulatory background and the potential policy implications.

Eco-Innovation Exchange Workshops: DASTI Bi-Lateral Network Projects

This proposal aimed to strengthen the research collaboration between the Center for Design Research at Stanford University (hereafter referred to as “CDR”) and the Department of Management Engineering at the Technical University of Denmark (hereafter referred to as “DTU”) in the field of sustainable product and service innovation, by adopting a collaborative, action-research approach to methodology implementation in international industrial companies. We ran a short workshop series, consisting of three intensive industry workshops, each with its own time for preparation and subsequent reflection/analysis. For the first two workshops (held in USA), we partnered up with two research-active, USA-based companies, Panasonic and Steelcase, who acted as the industrial participants for the workshops. Both CDR and DTU have a history of research collaboration with both of these companies and had therefore well-established connections inside both organisations. Previous collaborations include interviews, in-depth studies, student projects and workshop orchestration within a strategic area for the respective companies. The third workshop was be held in Denmark, where we invited three Danish companies to join the discussions and exercises, together with Panasonic and Steelcase. This project focused on two main research phenomena, sustainability and innovation, and aimed to begin to uncover the connections between the two in an industrial setting. It was our working hypothesis that sustainability demands for a globally active, industrial organisation can lead to innovative solutions in terms of business development opportunities. Also, it was our hypothesis that an organisation striving towards innovation will increasingly need to live up to the key requirements of sustainability. In the context of product development, sustainability has been an area of focus for some time now. The past two decades have seen many efforts from academia and industry alike, towards the consideration of sustainability during product development. The result is that there are now hundreds of guidelines, tools, calculators and consultants available to aid the process of design optimisation for sustainability. However, the project team's and other researchers’ studies show that companies’ uptake of these many tools is sparse. In terms of innovation, there are a plethora of theories and schools of thought regarding industrial innovation. These theories can be roughly classified in three main areas of technology-driven innovation (new things make new markets), user-driven innovation (seen from a traditional lead-user viewpoint) or idea-driven innovation (with focus on the creativity of the individual entrepreneur). In this project we made the first attempts at establishing a focus on sustainability-driven innovation. Our scientific research base was on the above-mentioned fields.

EIS - Strategic research alliance for Energy Innovation Systems and their dynamics - Denmark in global competition

EIS Strategic research alliance on Energy Innovation Systems and their dynamics carries out research analyses on energy innovation systems and connects leading researchers working on the topic. Through this, the alliance creates important new knowledge about the innovation systems and the roles they play for moving towards renewable and sustainable energy systems in the future. By active knowledge dissemination and interaction with societal stakeholders, the alliance is expected to contribute to strategy development and innovation in individual areas of energy technology as well as to policy and strategies on a more general level. EIS contains a row of sub-projects, including PhD projects and post-doc projects. It is funded by the Danish Council for Strategic Research, the Programme Commission on Sustainable Energy and Environment, primarily, and by the project partners. The alliance runs from 2011 to 2016.

Department of Management Engineering
Technology and Innovation Management
ACTUM
The objective of the project is to provide an activity-based framework that is able to capture and describe individual and household activity patterns within a multi-modal transport environment that is characterized by a diversity of travel mode combinations. An improved knowledge about individual and household activity patterns will increase the comprehension of behavioural responses to future transport policies (e.g., road pricing schemes and travel demand management interventions). Therefore, transport models developed on the basis of the research will provide more accurate responses to policy instruments than existing methods and facilitate a right way towards a sustainable balance between mobility and transport externalities. The ambition is to develop a theoretically consistent and coherent framework for activity-based modelling and forecasting of urban passenger transport. This includes (i) building activity chains for home and out-of-home activities, (ii) estimating how transport demand is derived from the activity chains, (iii) modelling the activity interaction between household members, (iv) capturing the timing of activities and their duration, (v) linking route choice with the choice of activities at the disaggregate level, and (vi) modelling long-term decisions with respect to, for example, car ownership as condition for forecasting daily activity patterns and travel decisions.

Drivers and Limits

Continued growth of car transport, rapid expansion of air travel, and increased freight transport makes transport the fastest growing source of greenhouse gas emissions worldwide. Advances in transport technologies leading to improved energy efficiency and reduced carbon intensity of fuels have been offset by steady increases in e.g.: demand of heavier vehicles, demand for leisure trips, longer commuting, and a growing role of high speed modes. This trend sets a distinct contrast with the greenhouse gas reduction target. Few dispute that solutions must be found to this problem, but there are significant uncertainties about if and how to intervene in transport demand growth in time, without damaging the economy. The aim of this project is to gain a deeper understanding into the drivers and limits of structural transport demand that can help determine how to reduce transport growth – and thereby climate and congestion effects - with minimal negative effect on the economy. We focus on four important themes in the description of the transport drivers: long distance trips; demography and socioeconomic; urban structure and infrastructure; and freight. Despite being four of the main challenges in transport growth, knowledge about their relative importance and the influence is not very well understood. The themes will be explored using both qualitative and quantitative methods. The theoretical foundations of the project comprise economic theory, spatial and environmental planning and social psychology. The empirical analyses will be based on existing transport databases combined with qualitative interviews and surveys. The outcome of the analyses serves as the basis for considering whether limiting trends can be expected in transport and how these may evolve over time. We formulate alternative visions and develop a scenario back casting process where alternative policies will be examined.

Healthcare Innovation Lab
Den 1. februar 2010 søsatte det tidligere Center for Sundhedsinnovation (nu en del af Videncenter for Innovation og Forskning) spydspidsprojektet "Healthcare Innovation Lab" som et Offentligt-Privat Innovationssamarbejde (OPI) mellem 26 partnere.

DTU bidrager til 2 prototyper og koncepter som direkte skal kunne anvendes og implementeres på relevante hospitalsafdelinger:

* Delprojekt A: Fremtidens Ambulatorium - Funktions- og organisatorisk planlægning:
At afstemme forskellige behov og perspektiver for patienter og sundhedsfaglige medarbejdere i et innovativt koncept for arbejdsgange og fysisk indretning af et ambulatorium. Gynækologisk ambulatorium på Herlev Hospital deltager i projektet.

* Delprojekt B: Mobilt overblik over prøvesvar:
At give klinikere og patienter overblik over status på prøvesvar og dermed øge patientsikkerhed/patienttryghed, kvalitet og effektivitet i klinikeres arbejdsgange samt hospitalsøkonomi. Gastro-endokrinologisk afdeling og akut modtageafdeling på Bispebjerg Hospital deltager i projektet.

Vietnam - Facilitating Implementation Readiness for Mitigation (FIRM)

Developing countries are requesting international financial and technical support to lay the foundations for and start implementing low carbon energy development paths rather than follow a business-as-usual fossil energy trajectory. In addition to reducing greenhouse gas emissions, additional benefits – employment generation, reduced expenditures on imports of fossil fuels, and improvements in local environmental quality, among others – provide strong arguments for adopting a low carbon approach to economic growth. The 'Facilitating Implementation and Readiness for Mitigation' project (FIRM) will help six to eight developing countries make a “quick start” on technology-based mitigation activities that are compatible with the evolving concept of Nationally Appropriate Mitigation Actions (NAMAs). FIRM will provide focused technical advice and strengthen the capabilities of energy and environmental policy makers and experts – and the institutions in which they work. The result will be the accelerated implementation of public and private mitigation projects within a NAMA framework, and reduced emission of greenhouse gases.

The Optimal Treatment of Waste

Affald udgør i dag en betydelig del af energiproduktionen i Danmark. Andelen forventes at stige i fremtiden, hvis affaldsmængderne stiger og energiudnyttelsen fortsat bliver bedre. For at kunne integrere blandt andet vindkraft er det afgørende, at det øvrige energisystem kan agere fleksibelt, hvilket især er en udfordring med affald. Øget liberalisering ændrer derudover rammerne for affaldshåndtering og dens regulering. For at kunne sikre opnåelse af mål vedrørende fx andelen af affald der genanvendes under de ændrede forhold, er det nødvendigt at udvikle nye beslutningsstøtteværktøjer til både affaldsforbrændingsanlæg og myndigheder. I dette projekt udvikles 4 typer værktøjer til planlægning af affaldshåndtering med fokus på både genanvendelse og energiproduktion. Til brug for affaldsforbrændingsanlæggene udvikles i samarbejde med et større affaldsforbrændingsanlæg to nye beslutningsstøtteværktøjer: en model der optimerer affaldshåndtering set fra et økonomisk perspektiv og en model der vurderer affaldshåndtering fra et miljø- og ressourcemæssigt perspektiv. Begge modeller optakleres til at håndtere nationale analyser til brug for nationale myndigheder. Dette kombineres med videreudvikling af to øvrige nationale modeller: en økonometrisk model til fremskrivning af affaldsmængder (FRIDA) og en energisystem analyse model (Balmorel). Dette vil gøre det muligt at analysere og vurdere betydningen af at anvende affald til energiproduktion i fremtidens energisystem.

Connovate - optimized building system using High Performance Concrete

Vision The parties will develop a new sustainable building system using High Performance Concrete (HPC) for sandwich elements. The system meets the visions of low energy use, low material consumption, material recycling and low CO2 emission throughout the entire life cycle, contributing to Denmark fulfilling its international obligations as well as expanding Denmark’s international position through export of an innovative building technology. The system will represent the next step in the construction industry’s increasing use of prefabricated elements, making it possible to offer the end user better solutions for insulation, increased living space and better indoor air quality at a competitive price. As a result of the superior performance compared to current refurbishment methods, the system is expected to play a central role in the foreseeable energy refurbishment of the existing building stock. Focused on global warming, this allows for legislation on the issue to be further tightened. Objective The aims are to develop and certify the basic elements for a new HPC building system and launch it on the Danish market prior to introducing the system to further markets. We will establish Connovate as a joint IPR holder and a company to develop business models for future development of products, markets and systems globally. IPR will be shared between Connovate, DTU and IPU and continuously strengthened throughout the development period supporting the core business. Success criterion The overall success criterion is to develop the basic HPC building elements and to create an effective production layout. A further criterion is the establishment of a company (Connovate) that on the basis of innovation and strong IPR’s will secure the continuity of developing the HPC system. A third criterion is to create jobs in a broad range of companies in Denmark and gain increased market share in export markets. Finally, we expect a measurable positive impact on the environmental challenges.

Green Energy and Low Carbon Development
The Danida Fellowship Course “Green Energy and Low Carbon Development” is a three-week training course to be held in Copenhagen, Denmark, 19 May – 6 June 2014. The course will explore green energy and low carbon development business opportunities in developing countries. The course is relevant for managers and decision makers from the private and public sectors seeking to develop their skills within improved energy efficiency, renewable energy and new markets related to trading in CO2 reductions. The course supports that new ideas are developed into realistic action plans for business development and enabling frameworks for public-private partnerships.

The course is being held for the 5th year in 2014. The contract is for one year at a time.

Innovation network for energy efficient and sustainable construction

The innovation network for energy efficient and sustainable construction - InnoBYG - is the innovation network of the construction industry in Denmark. The Danish Agency for Science, Technology and Innovation has granted a co-financing of 20 million DKK to the network.

InnoBYG brings the industry together across professional competency. The network has focus on knowledge sharing, networking and development of the industry among its members, both domestically and internationally.

Between 2010-2014 InnoBYG will facilitate the development of the construction industry by addressing a number of societal and technical challenges, all of which are related to energy efficiency and sustainability in the construction industry.

DTU Management Engineering is responsible for the subproject on development of sustainable business models in construction.

Climate damage modeling in LCA – quantitative sustainability assessment of future technologies

Climate change is a global threat to ecosystems and vast resources are invested to develop new climatically sustainable technologies. However, the assessments of such climatic sustainability are generally hindered by the absence of appropriate assessment tools of sufficiently broad scope. In the project we will develop "a concept for quantitative
environmental sustainability assessment of technologies (e.g. renewable energy) from a climate change and climate protection point of view. Financed by the Villum Kann Rasmussen Foundation

Improving Road Safety: Developing a Basis for Socio-economic Prioritising of Road Safety Measures

The aim of this project is to develop an improved basis for efficient socio-economic prioritising of road safety measures. Road fatalities and injuries are together with congestion the largest externalities connected to transport. The traditional way of predicting road accidents – and thus assessing road safety measures – has been to model accidents as a function of road type and traffic volume only. However, these variables cannot alone explain the trend in accidents over time and moreover, in traditional models the severity and accidents are completely decoupled. This project will overcome these shortcomings and combine the modelling approach with in-depth insight into road user behaviour. This project will use the aggregate and disaggregate parts of the so-called DRAG modelling approach to establish quantitative relations between accidents of various degrees of severity and road user (risk) behaviour, vehicle ownership, infrastructure and economic activity. Moreover, the project will estimate preference-based economic values of road safety measures. As a novelty, accident modelling will include both police recorded accidents and emergency room recorded accidents. In addition, modelling will include individual socio-economic and demographic data from the entire Danish population. Finally, a more qualified inclusion of human behaviour factors, i.e. road user sub group behaviour, in the models will be possible. Methods range from in-depth interviews to statistical modelling. The project is organised in five work packages (WPs), each with defined tasks and scope. Thus, data for WP3 will be documented and provided by WP1 and 2; modelling will take place in WP3, qualification of the models in WP2, development of a scientifically founded valuation method of accidents in WP4, and eventually transforming results into recommendations in WP5.

Innovation Consortium PROTEUS: PROduct/service-system Tools for Ensuring User-oriented Service

The Innovation Consortium, PROTEUS, is working to jointly develop new knowledge about how after-sales service can be effectively integrated into business development and industrial organisations, so as to become a source of revenue, rather than a cost to the company. The participants in PROTEUS are interested in understanding, through examples, how to effectively and systematically integrate service development into their product development and business creation processes. State-of-the-art: Current literature on Product/Service-Systems (PSS) includes examples of procedures for the integration of product and service features in product development, but these approaches do not consider a number of key areas for business, such as the commercial considerations, the strategic organisational issues, or the possibilities of collaboration across the value chain. PROTEUS is in a unique position to begin to address some of these issues on a whole branch.

Workspace Design II: Development of a new design practice in engineering consultancies and architectural firms

The objective is to develop and test methods and tools for a new dialogue oriented design practice in architectural firms and engineering consultancies aimed at involving users and occupational health and safety considerations in the early design stages.

Case studies are accomplished in collaboration with an architectural firm and an engineering consultancy. A single case study includes intervention in an ongoing engineering project. Other case studies include a systematic evaluation of completed design projects.

The project outcome includes a handbook for architects and engineers. The handbook is developed in an iterative prototyping process with professionals from architectural firms, engineering consultancies, and occupational health and safety consultants.

HEALTH CARE INNOVATION LAB: Development and test of simulation methods in a hospital outpatient clinic

The objective was to develop and test simulation methods and tools as a means in user driven innovation. The case was a hospital outpatient clinic that was going to move into a new building within 4-5 years. The research team planned and facilitated a number of design and simulation workshops with a user group including two medical doctors, two nurses, and a secretary.

The results included a new cost-effective method of scenario-based tabletop simulation, which successfully promoted innovation and improvement of health care systems.

In the case the user group succeeded in developing an innovative concept of the future outpatient clinic in terms of spatial layout, work organization, knowledge sharing, technology, and finance.

Enabling and governing transitions to a low carbon society

Sustainable Transitions is a cross disciplinary research alliance comprising of research groups at the Technical University of Denmark, Aalborg University and the Business School Aarhus University in cooperation with research groups from universities in Eindhoven, Munich and Nottingham. The project operates on five core societal arenas for transition: Market regulation, Household consumption, Innovaton dynamics, City structure and transport, and Legislation on biomaterials. Through historic analysis, case studies and action research the alliance will develop knowledge and methods that can support different actor's engagement in societal and technological transition processes reducing the use of fossil energy.

Supported by the Danish Council for Strategic Research.

Enabling and governing transitions to a low carbon society : Sub project B: Challenging regimes at the level of everyday life in household practises

This project will explore the challenges and potentials in the meeting between regimes of the energy system and the normalised practices and visions formed at the level of households. A future sustainable energy system depends on the management of the very complex system of production and consumption across geographical, organisational, and time scales, and a successful integration of the large number of households in the system constitutes a crucial challenge. The diffusion of 5 technologies for intelligent management of the home holds an increasing technological potential for stronger coupling of the energy supply system and the energy consumption of households. These potentials have been present for quite some time without being realised. This frames a series of interlinked technical perspectives regarding peak loads, buffers storing, energy renovations and households as energy producers. Exploiting the potentials in different ways challenge visions of comfort as well as lived everyday practices and norms. Studies show that efforts to minimise energy consumption in dwellings typically are caught up by rising sizes of dwellings, levels of comfort, and numbers of electrical appliances (Quitzau and Rapke 2008). Hence there is a need to develop a more complex understanding of how domestic practises involving energy use presently change, and how governance strategies to implementation of energy saving measures may interact with these changes. Furthermore, it is important to highlight the interaction between energy saving initiatives from actors outside households and initiatives taken by the consumers themselves.

Performing Temporary Spaces for User-driven Innovation: subprojekt - Municipality platform  
The project is a sub projekt of the TempoS Alliance in which the partners coming from DTU, DKDS (The Danish Design School) and CU (University of Copenhagen) have a common focus on user involvement in innovation. The research takes the outset in the identification and performance of temporary, provisional spaces where a variety of actors are assembled with the aim of fostering innovation through an engagement with existing and imagined practices. This part of the project takes the outset of the municipality as the platform for innovation and focuses on the user in the role of citizens. The project is developed in collaboration with the municipality of Copenhagen. A PhD projekt constitutes the main contribution. See Peter Munthe-Kaas. From the Tempos application: In contrast to most previous work on user-driven innovation our approach does not hinge on the existence of established communities of users, which designers can ‘tap into’ and interact with. Our research will explore situations where the staging of temporary spaces for innovation can lead to the creation of new practices and emerging artefacts through open-ended interaction. The alliance’s draws on actor-network-theory, practice theory, social learning and design research underpinning that innovation entails series of translations. The research is organised in three phases: 1. Drawing on the partner’s earlier research complemented by an overview and analysis of contemporary approaches to user-driven innovation the alliance’s methodology will be refined. 2. The core of the research will be organised within four projects each emphasising a specific mode of inquiry and covering a number of different sites for user engagement. The projects study how users and innovations are co-constructed within temporary spaces and will produce a repertoire of methods that can help understanding and support co-creation. 3. The activities will be finalised with a synthesis and outline of how to stage and improve design education, design practice, and innovation management. The alliance collaborates with international researchers and facilitates exchange through publications, seminars, and international conferences. All partners are engaged in education and professional training opening for continued interaction with students and practitioners in design and innovation.

Innovation and Sustainability  
Department of Management Engineering
Pre-hospital Care and Intervention in the Urban Workspace

The project engages practitioner insight and actual practices of pre-hospital paramedical work in channeling these towards the design of repertoires for paramedic practice to support their work. The pre-hospital domain is influenced by conditions to which paramedics often have little influence. Paramedics are called to render their expertise and services accessible to potential victims or patients, and they work in what may be regarded as spaces, which have been pre-configured or organized for anything but the purpose of their reaching and attending to the patient at the site of emergency. While devices for intervention and treatment, including the ambulance and its auxiliary facilities are, to some extent designed to be conducive to managing the complexity and at times unanticipated conditions, the conditions, which paramedics must confront and conduct their work in, also call upon them to draw on their practical experience or improvisation.

Ethnographic work of pre-hospital intervention practices can yield insight into the complex skills, these paramedics evoke in their knowledge and work practices, engaging with the urban setting (public spaces, private households) as their workspace. The multisite ethnography is drawn upon, to allow for insightful situations to shed light on how paramedics evoke their skills in the light of limitations that the different settings of practice in the urban space places on their work. The issues raised through the field work will be generated into a platform for action research, engaging selected practitioners in a focused exchange of ideas about conceptualisation and renewal of practice.

Innovation and Sustainability

The 18th International Conference on Engineering Design, ICED11: Impacting Society Through Engineering Design

ICED11 Theme: Impacting Society Through Engineering Design Design has a central role in bringing engineering and technology to practical use. We have chosen, therefore, that ICED11 will focus on balancing the societal impact of engineering design. Message from the Chair On welcoming you to the eighteenth International Conference on Engineering Design, ICED11, it can safely be stated that engineering design research is firmly established as a strong research discipline. As design researchers, design practice is our research object and industry companies are our research laboratories. Based on our observations, discussions and participation in design activities, we gather knowledge and insights and crystallise these into both academic models and practical methods. Our customers are students, training to be the product developers and innovators of the future, and industrialists, engaging with us to get insight into tools and methods, which fit to their practices and empower them to meet the challenges of global competition. The theme we have chosen for ICED11 is Impacting Society through Engineering Design. Design has a central role in bringing engineering and technology to practical use. We are expecting that each of the papers and presentations at the conference will provide its own contribution to the ICED11 theme. We’re delighted to see the variety and the quality of contributions that our colleagues from the design research community have submitted to ICED11. In its 30 year history this is the first time that an ICED conference has returned to the same city, “Wonderful Copenhagen”. In the Danish official ‘Year of Design’ the city is the perfect conference location, hosting the highest quality design, ranging from industrial design, through stunning architecture, to a dynamic engineering design industry, which has extensively backed ICED11. We have taken great care to create a conference showing leading edge research into engineering design and product development practice and to provide a lively backdrop for knowledge exchange and research discussion. Our goals with ICED11 have been to place particular emphasis on industry participation, provocative and relevant keynote speeches, maximum time for debate and discussion, and space to go in to depth, via the SIG workshops. And all this with a Danish flavour, which we hope you find welcoming, fun and “hyggelig”! Welcome to ICED11!

A Guidebook for Sustainability Performance Measurement for Transportation Agencies
This guidebook provides state departments of transportation (DOTs) and other transportation agencies with a practical and easy-to-use approach to identify and apply sustainability-related performance measures, some number of which may already be integrated into agency business practices, to produce a new lens through which decision makers can view their agency’s performance. It describes the underlying principles of sustainability as it relates to transportation, possible goals that can be used to address those principles, and performance measures that can be used to address those goals. Aspects of sustainability-related performance measures, including data sources and examples of use, are discussed. A reference compendium of performance measures has also been provided. This guidebook should be of immediate use to those who have mastered the basics of performance measurement and who are familiar with their own agencies’ performance measurement program, but who are challenged with providing useful information to agency leadership on how effectively their organization is meeting or can meet sustainability goals. Examples from DOTs, private industry, and Europe illustrate how sustainability can be successfully added to an agency’s extant performance measurement system.

The Transport Innovation Network (TINV) is a national, cross disciplinary network aimed at the Danish Transport sector. The primary objectives of TINV are to create synergy, encourage match-making and generate research and development projects between stakeholders in the transport sector and research- and educational institutions, as well as related sectors such as energy and infrastructure. Denmark’s competitive position depends on the technological leadership of the transport sector. Accordingly, it is paramount for the Danish transport sector to be able to draw on the latest technology knowledge and research. Through a number of sub-activities, TINV works to gather the different players across the transport scene with the aim of creating synergy, identifying the need for new technologies and initiating projects between our members to ensure development and implementation of these. The Danish shipbuilding industry has traditionally focused on delivering products to their customers, based on the longevity and high technical/functional qualities of their physical artefacts. But as with most industries, the continuing market globalisation in the shipbuilding industry both opens opportunities, in terms of a rising number of potential customers and represents threats, due to the growing number of competitors worldwide. Maritime component manufacturers are experiencing a growing demand from customers with respect to after-sales service, and they also see a great business opportunity in becoming more systematic about their integrated product/service development activities.

One Display for a Cockpit Interactive Solution
European FP7 project aimed at developing a single display cockpit by employing state of the art technologies.

The ODICIS project aims at developing a single display cockpit associated with adequate means of interaction. The concept of use of such a display will be investigated and followed by a Human Machine Interface development.

This addresses three current major aeronautics needs: the system architecture flexibility, the useful surface optimisation and the information continuity. Therefore the project will improve the operational safety and efficiency while reducing the aircraft development cost.

The first objective is to prove the technical feasibility of an avionics large seamless display, which can possibly be curved. This involves optical but also graphic generation challenges. The design of the display must take into account as much as possible user wishes and aircraft possibilities.

Once the display is available, the proper means of interaction must be defined and implemented. At this point, a complete
technological mock-up of a single display cockpit will be available.

Meanwhile, the concepts of use, that stimulated the idea of a single display cockpit, will be reviewed, deepened and tested on the mock-up. Human factors evaluations will seek to ascertain the safety and efficiency gains produced by this novel cockpit concept based on use of a single display.

The ODICIS consortium comprises 9 partners from 7 EU member states. It includes 4 large companies, 1 SME, 1 research centre and 3 universities. Together they provide the range of key skills, knowledge and experience required to define, develop, implement and exploit the results of the ODICIS project.

Project

The EcoMobility project
The Øresund EcoMobility project’s purpose is to promote sustainable and climate friendly transport solutions. Throughout the Øresund region, there is profound knowledge and many competencies on the subject “climate friendly transportation”. Øresund EcoMobility Knowledge & Innovation Centre strives to gather these competencies in a unified network of universities, industries and regional authorities. This unique network of regional competencies, will consist of over 40 experts within areas such as: cleantech, environmental science, infrastructure, city and transport planning, logistics and supply chain management. The project was built on three stages:

1. Cross-science Triple-Helix Thematic Knowledge Exchange Networks which gather knowledge on climate friendly transportation of goods and people.

2. Øresund EcoMobility Knowledge & Innovation Centre, which carries out knowledge dissemination, innovation and competence building.

3. Øresund Competence Building and Knowledge Sharing activities, such as publications, websites, workshops, conferences and courses for professionals, university students etc.

The DTU team developed the EcoMobility model as part of its project contribution.

Nanolifecycle: A LIFECYCLE ASSESSMENT STUDY OF THE ROUTE AND EXTENT OF HUMAN EXPOSURE VIA INHALATION FOR COMMERCIALLY AVAILABLE PRODUCTS AND APPLICATIONS CONTAINING CARBON NANOTUBES

1) This study is aimed at analysing the likely route and extent of human exposure to carbon nanotubes (CNTs) via inhalation for a set of representative CNT-containing products in a lifecycle perspective. 2) The study has been conducted by the Safety of nanomaterial Interdisciplinary Research Centre (SnIRC), led for this study by the Food and Environment Research Agency, with participation of other Academic and Industrial Experts. 3) As part of the study, a review of all available CNT-containing products was carried out, and a representative subset of the products was identified for exposure analysis. The three CNT-containing products selected for the study included lithium-ion batteries, epoxy adhesive resins, and textiles. 4) The study assessed the suitability of current lifecycle assessment (LCA) protocols for assessing inhalation exposure from CNT and other nano-products. The relevance and adequacy of the relevant ISO protocols was assessed in relation to nanotechnology products (especially CNT-containing products), and any inadequacies have been highlighted. 5) The study also analysed the possibility of exposure to CNTs arising via inhalation during all stages of the life cycles of the selected study products. 6) The findings of the study indicate that: 6a) LCA is not a tool for exposure assessment. On the contrary, exposure assessments can provide information to LCA that is relevant for impact assessment of CNT releases. LCA is, however, useful in identifying the stages in the lifecycle during which exposure may be relevant. 6b) There is an almost complete lack of data to enable both a full-scale LCA, or a quantitative exposure assessment. Due to unavailability of the required data, a simplified LCA approach is adopted in this study,
focusing on the potential inhalation exposure during the lifecycle of the selected CNT-containing products. Also, the exposure assessment is limited to qualitative analysis because of the lack of data necessary for a quantitative assessment. (Both LCA and exposure analysis have shown that the material synthesis stage (both for CNT materials, and CNT-containing products) is prone to giving rise to inhalation exposure to CNTs. However, the few studies carried out so far have generally shown that nanoparticle emissions during synthesis can be effectively controlled through appropriate engineering measures. Significant inhalation exposure to CNT material at this stage should be preventable provided such processes are carried out under appropriate emission control and waste management procedures. The main emphasis from the exposure point of view, therefore, needs to be on other stages/ processes in the lifecycle of products, where any sophisticated emission control measures are not likely to exist, e.g. during handling, transportation, accidental release, and use and disposal of the relevant materials and products. (Using the currently available level of scientific evidence, those stages in the lifecycle of each study product have been highlighted where inhalation exposure to CNT is possible. (In brief, the study has indicated that during post-production lifecycle stages: 9a) CNT-containing batteries will carry a risk of inhalation exposure during use only if the batteries are physically cut open. The main likelihood of exposure exists during accidental release (e.g. fire), and during recycling and disposal stages. People likely to be exposed will be those working at the recycling or waste disposal premises, or in the immediate vicinity. 9b) The use of the textiles, to which CNT is added on the outer surface of the yarn in a post-production coating process, is likely to pose a greater potential for exposure to CNT than any of the other processes studied. This is the only case where a significant consumer exposure during use stage seems plausible. Other lifecycle stages where there is a likelihood of exposure include recycling (shredding and milling of worn-out textiles), and disposal through incomplete incineration. Thus those likely to be exposed would include those working at the recycling or waste disposal premises, or in the immediate vicinity. 9c) CNT-containing epoxy adhesive resins may carry a risk of inhalation exposure during use only if there are conditions that lead to formation of aerosols. The main likelihood of exposure will be during disposal through incomplete incineration. It is also of note that epoxy resins generally have a relatively short shelf life (9 months in the case of the study product). There is therefore a need to develop a mechanism for appropriate disposal of the unused (unhardened, liquid) epoxy resin for appropriate disposal. 10) Common to all the three product types studied is the need for mechanisms for appropriate end-of-life treatments (e.g. separate collection of (spent) CNT-containing batteries, recycling of CNT-containing batteries and textiles under controlled conditions, and processes that ensure complete incineration of CNT in the disposed of products). 11) Urgent research is needed to address the almost total lack of exposure data for CNT-containing consumer products, and the appropriateness of end-of-life treatments. The findings of the research would also enable the manufacturers to develop safer products through better designs that are aimed at minimising the likelihood of exposure to CNTs (and/ or other nanomaterials) during subsequent stages in the lifecycle.
Malawi and Botswana - African Caribbean and Pacific (ACP) Multilateral Environmental Agreements (ACP MEA), CDM component

This project is part of the European Commission Programme for Capacity Building related to Multilateral Environmental Agreements (MEAs) in African, Caribbean and Pacific (ACP) countries. The UNEP Risø Centre (URC), based in Denmark, is the project implementing agency for the Clean Development Mechanism (CDM) sub-component. The project, hereafter referred to as EU-ACP-MEA, will be implemented over a three year period, starting on 1 February 2010 and ending on 31 January 2013. Following expressions of national interest the CDM sub-component will be implemented in seven African countries: Angola, Botswana, Ivory Coast, Malawi, Nigeria, Rwanda and São Tomé and Principe, three Caribbean Island States: Belize, Cuba, Trinidad and Tobago and the following Pacific countries: Fiji, Papua New Guinea, Samoa, Solomon Islands, Tonga, Vanuatu and Timor Leste.

Engineered and designed nanoparticles (NPs) may pose a potential risk to human health and to the environment. The availability of results from relevant and systematic cross-disciplinary research is poor. Physico-chemical characterization and quantification should be incorporated among other parameters. It is mandatory to gain systematic knowledge before we are able to assess risk to humans and to the environment. The main purpose of this networking project is to establish a forum to gain and share such knowledge. The division for Toxicology and Risk Assessment (div. T) has a more than thirty years tradition for toxicological advice and risk assessment based on own interdisciplinary research and is a national and international leader in these areas. The division of Food Chemistry (div. K) has expert knowledge about chemical analyses in biological materials and testing of migration from food contact materials. Recently acquired knowledge includes studies of metal microparticulates and elemental speciation in food and biological matrices. Internally in the National Food Institute, div. T and K have established a thriving network that includes complimenting scientific skills useful in the cross-disciplinary area of nano research. Div. T and K are establishing national and international networks, presently including Danish governmental institutions and universities, and private companies. For the time being a.o. The Danish Food Agency, Danish Environmental Protection Agency, Aalborg University, University of Illinois, Risø National Laboratory, and DHI - Water and Environment are taking part. DFVF also is a member of two national nanotechnology networks: NaNet and iNANO. This thriving network has initiated initiatives for research including physico-chemical characterization and quantification and in vitro testing and has planned in vivo investigations. We can offer collaboration with other institutions in EU countries or elsewhere.

Environmental Care: City Toll Systems

The project assumed a Road Pricing scheme is to be implemented in a major city, and will then offer support as to which scheme will yield the most benefit to that particular city. (exemplified for Copenhagen). In short, the objective of this project is to construct a tool (hereafter referred to as 'the Tool'). This incorporates the development of a methodology which allows the comparison of economical and ecological effects of a road pricing scheme. The tool that can be used to evaluate a set of different Road Pricing schemes based on various parameters and then answer the following three questions: from a customer’s point of view: 1. What Road Pricing scheme will yield the best results for the city? 2. What are the effects of the Road Pricing schemes compared to a given situation (which could be the current situation? or a situation in future)? 3. What are the answers to the above two questions in a near future scenario? (2 to 5 years)? The Tool will answer the above three questions with KPI’s within the areas pollution, revenue and traffic. Pollution will primarily be measured by airborne pollutants (incl. CO2 and particulate matter). Revenue will be the income from road users’ payments to the Road Pricing scheme minus the cost of establishing and maintaining the scheme. Traffic will be primarily measured by average speed and congestion. A future scenario is defined by the input parameters. As such there is no limit as to how far into the future the tool can be used, but the results are of course dependent on the accuracy of the input. The Tool will initially be able to evaluate three different Road Pricing schemes: 1. Distance based Road Pricing where the pricing is a function of the distance driven within a zone. In this case the Road Pricing scheme is based on GPS in possible combination with a secondary technology for enforcement such as camera or RFID. 2. Fixed zone based Road Pricing where there is a fixed price for entering a zone. The technology here can be GPS, RFID, camera or another stationary technology. 3. Flexible zone based Road Pricing where the price for entering a zone is dependent on the time of day the zone is entered. Technology can be as in (2), but additional displays informing of the price might be needed. The baseline scenario that will be used when evaluating the above three Road Pricing schemes will be the KPI’s from running the Tool with a no pricing strategy. The results showed that a mixed base pricing (mixed by 1 and 2 above) provides the best results in terms of increased average speed and less congestion as well as in terms of reduction of CO2 emissions (4.5% reduction) and human health impacts in the inner city.

Evaluation of Interventions towards Young people in school food programs, EVIUS.

The project aims at evaluating the effects on children of different healthy school food interventions. The project consists of several work packages with the following research questions: WP1 - Diet & Nutrition: Does the school food have an effect on the student's dietary intake? Is dietary intake different for students in different age groups? WP2 - Coaching & counselling: How can coaching of intermediaries be developed to efficacy. Does coaching of intermediaries have an effect on dietary intake? WP3 - Learning & preferences: How does the school food environment influence the learning climate? How do the school food environment influence the well-being and concentration of the students? WP 4 - Sociotechnical approach to school food: What type of meaning and sense does teachers and students attribute to different school food concepts? What organisational and social pre-conditions are needed for the long term survival of school food programs? Does price have an effect on the students demand and use of the school food programme?

Policy Influence of Indicators

The overall aim of the POINT project is to help find better ways of using indicators in all aspects of policy, but with a thematic focus on the role of indicators in policy processes fostering and supporting change in areas of ‘Sustainable Development’ policy, including how environment is integrated in other sector policy areas.

**Environmental improvement through product development**

Companies in Denmark and abroad are working increasingly to reduce human impacts on the environment and nature. At the same time there must still be a large focus on the creation of value for customers and consumers. This development gives rise to a huge potential for Danish companies, to create new business opportunities, where sustainable development and value creation are integrated early in the design of new products and services. There is a great opportunity for businesses to create a new and positive agenda, where the focus is on all the good that companies can do for the environment, society and economic growth. Such an agenda must, of course, be based on a high involvement of the competencies of the companies’ own employees, as well as those of partners in the value chain. The Danish Environmental Protection Agency and the Confederation of Danish Industry are cooperating on this project with DTU and IPU, to promote and aid the establishment of such a new agenda. Focus is placed on how products and services can be designed so not to harm humans, the environment and nature. The project's main result will be a Guide to environmental improvement through product development. The Guide will give inspiration and a stepwise approach to integrating positive environmental effects into companies’ design and product development processes. The Guide is intended primarily to aid product developers who have the task of building environmental thinking into the product development process. However environmental staff, industrial designers, manufacturing staff and others can also benefit from reading the Guide. The project will start with a review of the environmentally-oriented methods used and product development activities carried out in Danish and international companies, as well as experience gained through a series of workshops with Danish companies. This project is financed through the Danish Environmental Protection Agency’s company funding scheme.

HYdrological Modelling for Assessing Climate Change Impacts at different Scales

HYdrological Modelling for Assessing Climate Change Impacts at different Scales (HYACINTS) has developed new methodologies and tools for assessing climate change impacts on water resources at different spatial scales. The main project components were:

- Coupling of DMI's regional climate model HIRHAM and DHIs hydrological modelling system MIKE SHE and conversion of GEUS' national water resources model to run in the coupled system aiming at reducing simulation uncertainty.
- Development of methodologies for using a spatially refined model grid in parts of a model domain where more detailed descriptions of hydrogeological conditions are required. An SME project on digital geological modelling was associated to this component.
- Development of methodologies for estimating precipitation and evapotranspiration from satellite data, particularly aimed at application in data poor regions in the world
- Assessment of uncertainty propagation in the calculation chain (emission scenarios→global climate models→regional climate models→downscaling/bias correction methods→hydrological models→hydrological change) and identification dominating sources of uncertainty in projections of climate change impacts on water resources.

Life Cycle Assessment in Developing Countries and Governance in Global Value Chains

Focussing on Life Cycle Assessment (LCA) tools, the research concerns the capacities which developing countries need to build to adjust to environmental standards and thus increase their access to international markets. It will identify the efforts to be undertaken by the developing countries as well as the interventions to be initiated by developed countries as part of their programmes of international development cooperation.

Evaluation of food safety management systems in the Danish school meal sector

This project focuses on HACCP-based own-control systems in the catering industry, using the Danish school meal sector as an example. The background of the project emerges from an assumption that the management tools used by SMEs not always lead to the wanted consumer safety. The food safety systems and technologies used are often not adjusted to practise and are not fitted to the daily routines in the SMEs. Therefore, HACCP-based own-control systems may obstruct the innovation, may be inappropriate implemented or may be detached from the other management systems in SMEs. Finally, HACCP-based own-control systems may also be technologically over-dimensioned resulting in poorer eating quality. The aim is to evaluate the efficiency of food safety management systems in SMEs in order to improve and simplify them.

PhD Supervision Collective for Sustainable Product Innovation

Sustainable Product Innovation (SPI) is a young but rapidly expanding research field, especially in the areas of environmental product assessment and design for environment. It has evolved from end-of-life focused approaches towards prevention through cleaner production and eco-design. In industry too a number of pro-active companies changed their controlling and complying posture in the direction towards a more preventive and strategic attitudes on environmental issues. The emphasis on environmental issues thereby shifted over the years from a more technical approach towards more organisational aspects of sustainable design. Whereas in recent years, the balance between ecological and economical considerations have been subject of research, a growing attention for social matters has resulted in this becoming a third component of what is now understood to be design for sustainability. Thus, sustainable product design is product development in which the three aspects of the ‘triple bottom line’ – the economical, environmental and societal sides of design (or profit, planet and people) – are increasingly taken into account. The first academic scholars that, in the mid 1990s, earned their PhD degrees in this field were often supervised by professors without any academic upbringing in this field. Generally, these professors had backgrounds in traditional technical, natural science or social disciplines, in either academia or industry. This also meant that these pioneers did their research in the context of a variety of disciplines and scientific environments, without the ability to rely on a common research culture, norms, methodologies, a large body of previous research, or even a network. In many ways, research in sustainable product innovation in the period 1992-2002 was of a grounded and explorative nature. The scholars who earned their PhD degrees in this field five to ten years ago, are today’s supervisors of PhD research. These people do have the academic background and network in the field, but are often young and relatively unexperienced in supervising PhD students. Regular courses in scientific research and supervision training may offer tools to develop general PhD research supervision skills, but likely, such skills are to benefit from systematic consideration of experiences from fellow supervisors. This view is strengthened by the fact that, as Sustainable Product Innovation is still a relatively small field and multidisciplinary of nature as well, academic activities in these fields are often housed in environments that only provide one perspective, such as mechanical engineering, chemical process technology, industrial economics, machine design, product design, industrial ecology, or business management. Therefore PhD candidates as well as their supervisors are often surrounded by only few colleagues (or sometimes none) those meet the same academic challenges, e.g. building further on a research tradition, making use of previous departmental research results, using similar theoretical frameworks and similar networks.

Healthy CanteenTakeAway at workplace
The idea behind CanteenTakeAway (CTA) is that healthy eating can be promoted by increasing accessibility of healthy meals from workplace canteens. The aim of the workpackage at the National food Institute is to develop and validate a novel canteen index and to use this tool in the evaluation of the effectiveness of improving the dietary intake among selected employees.

Renewable Electricity Supply interactions with conventional POwer generation Networks and Demand
Supported by Intelligent Energy Europe

The envisaged increase of electricity generation from renewable energy sources (RES-E) of intermittent nature like wind and photovoltaics will increase electricity system costs dramatically. As a result, the European renewable energy target is not likely to be achieved in 2020 in case no system cost reducing measures are taken. Therefore, RESPOND developed policy responses and regulatory framework improvements in order to integrate RES-E more optimally in different segments of the electricity system; generation, trade and balancing markets, demand, and networks. Results were successfully presented at conferences and policy meetings in Brussels, Vienna and Leuven aimed at European and national policy makers, regulators, TSOs, DSOs, renewable generators, suppliers and other power system actors.

Biopolymer nanocomposite films and food packaging

Plastics produced from biodegradable polymers such as polylactide (PLA) are of increasing commercial interests. They are manufactured from renewable resources such as agricultural products and have the potential to meet environmental requirements. However, a wider use of PLA in food packaging requires further material development in order to achieve the necessary stability and permeability profile to gas or water vapour. In the NanoPack project we will investigate improvement of PLA properties through nanoscale reinforcement using reinforcing fillers based on natural clay silicates and metal hydroxides. The National Food Institute will characterise nanoparticles migrating from PLA film and perform in-vitro and in-vivo toxicological studies on relevant effect parameters. A thorough risk characterisation in the context of their use in food packaging will be performed by integrating results from exposure estimates and toxicological studies.

Project

Renewable energy in the transport sector using biofuels as energy carriers
Biofuels, especially ethanol, have been in political focus for the last couple of years, both internationally and in Denmark. For the European Union, the EU Biofuel Directive has set a target of 5.75% by 2010 for the biofuel share of transport fuels. This has resulted in a couple of projects examining the impacts of biofuel introduction, by looking at individual production processes or lifecycle analyses of single technology applications. However, no detailed analyses of the nationwide implications in terms of changes in emissions, land use and other environmental effects have been undertaken to date. This project applies a scenario approach to investigate the abovementioned effects for Denmark. Three different transport fuel scenarios, a business-as-usual scenario, an EU policy scenario that adheres to the targets outlined in the EU Biofuel Directive and an impact-adapted scenario will be described. The impact-adapted scenario will incorporate the results of the two previous scenarios and outline a sustainable option for biofuel introduction in Denmark, taking into consideration and examining mitigation of, where possible, the negative implications for the environment and land use.

SCGE for freight
Project for the ministry of transport concerned with the development of a SCGE freight model to evaluate roadpricing for trucks

Driving under the Influence of Drugs, Alcohol and Medicines
The road transport system is one of the most hazardous and most expensive in terms of human lives in the European Union. As the EC White Paper suggests, the present level of investment in road safety fails to reflect the severity of the situation. Currently the EU spends less than 5% of the total cost of those accidents on developing safety countermeasures. However, a modern European transport system capable of upholding sustainable development within the EU must be reliable, safe and efficient. As consumption of psychoactive substances such as alcohol, drugs and certain medicines are likely to endanger the drivers aptitude and impaired driving is still one of the major causes for road accidents, some active steps have to be taken to reach the goal of a 50% reduction in the number of road deaths in the EU. The objective of DRUID is to give scientific support to the EU transport policy to reach the 2010th road safety target by establishing guidelines and measures to combat impaired driving by - conducting reference studies of the impact on fitness to drive for alcohol, illicit drugs and medicines as well as giving new insights to the real degree of impairment caused by psychoactive substances and their actual impact on road safety and generating recommendations for the definition of analytical and risk thresholds, - analysing the prevalence of alcohol and other psychoactive substances in accidents and in general driving, setting up a comprehensive and efficient epidemiological database, evaluating "good practice" for detection and training measures for road traffic police allowing a legal monitoring of drivers, - establishing an appropriate classification system of medicines affecting driving ability, give recommendations for its implementation and
create a framework to position medicines according to a labelling system, - evaluating the efficiency of strategies of prevention, penalisation and rehabilitation, considering the difficulties of appropriate evaluation strategies for combined substance use and recommend “good practice”, - defining strategies of driving bans, combining the road safety objectives with the individual’s need for mobility, - defining the responsibility of health care professionals for patients consuming psychoactive substances and their impact on road safety and elaborating guidelines and make information available and applicable for all European countries.

DanWORM - Danish version of Working on Occupational Risk Model : Accident prevention using ORM

The risk perception in SME’s is normally low, which is closely related to the relatively few accidents that the small enterprises experience by themselves compared to larger enterprises. This is a fact even though the SME’s together represent a higher accident frequency compared to large enterprises. To reach the SME’s we have to find a way to support them because they normally do not have time nor the resources to get the necessary knowledge and awareness for working with their own safety. The Dutch developed WORM project is transferred into a Danish context, with the aim to create a more simple system targeted the SME. The WORM project develops a method that identifies the activities in a person’s daily work that contributes most the person’s risk and also identifies what conditions need to be changed in order to reduce that risk. Our investigation seeks to answer the question whether we can collect information about the risks in SME’s using the WORM method and whether we can find a way to present this information so that the SME’s will be able to use the information constructively. Finally we want to evaluate the impact of this method on occupational safety in SME’s, because the investigation also focuses on the management factors that can motivate the SME’s to increase their risk awareness and own initiatives. The project is carried out for three occupations, carpenters, caretakers, and blacksmiths, all working in enterprises with less than 50 employees.

Rapport om fremtidens fjernvarme
Rapporten afdækker 2 problemstillinger:
1. Hvad findes der af eksisterende rapporter, udredninger og analyser, der belyser fjernvarmes rolle i fremtidige energisystemer og/eller fremtidige perspektivfrie fjernvameløsninger.
2. Hvilke rapporter, udredninger og analyser om fjernvarme er der behov for som indspil til scenarier og overvejelser om fremtidens energiforsyning med hensyn til at sikre, at de mulige gevinst, som fjernvarme kan bidrage med, ikke overses på bekostning af mindre hensigtsmæssige (energieffektive) energisystemer.

Innovation C.I.R.C.U.S.
The objectives of this project are to examine and identify the driving factors behind innovation, to involve and tap into all potential stakeholders in society and to leverage good practices and new measures into national and regional innovation policies. Activities carried out within the project include an identification of all potential innovators in society, from school children to advanced research laboratories and from the curious human being to front-runners among innovative enterprises. Innovators of all levels will be brought together and public-private innovation partnerships will be promoted.
The aim is to enable an exchange of experiences and attitudes towards creativity, promote new constellations of collaboration and enhance inventiveness within and across business sectors, scientific fields, education, public sectors and virtual communities.

Transportation revenue management
The purpose of this research project is to develop new and improved optimization models and algorithms within the area of revenue management (RM) in transportation. The project is funded by the Danish Research Council for Technology and Production Sciences under research grant 274-06-0244. In this project we are concerned only with schedule-based
transportation, i.e. transportation networks where service is available only at designated times. The transportation service is not available after its designated time and cannot be stored, i.e. the service is perishable. Another characteristic of the means of transportation we are considering is that the capacity is fixed, e.g. number of seats in an aircraft or number of slots in a container vessel. The breakthrough in RM came in the airline industry when it was recognized by an airline company that they produced seats at a marginal cost near zero because most of the costs of a flight are fixed. The objective of the transportation firm is therefore to minimize the amount of available capacity at the start of service. The capacity control problem is concerned with the optimal allocation of capacity to different classes of demand that occurs over time. A complicating factor related to the capacity control problem is the uncertainty of the demand forecasts. Therefore, the capacity control problem needs to be re-optimized when the forecasts are changed. It is critical that the optimization of the capacity control problem is computationally efficient in order to be implementable in practice. This project is focused on two areas of RM where there has been relatively little research, i.e. the problem of handling batch bookings and the multiple-resource capacity control problem. The purpose of this project is also to extend the RM theory and methodology to container liner shipping.

East - West project : Danish WP3 Report
The Danish parts of WP3 are to perform a pre-feasibility study, including urban planning, environmental impact and capacity issues, for: •Road and railway connections to the port of Esbjerg •A intermodal terminal at port of Esbjerg The main objective of the Danish part of WP3 is therefore to perform and report these Danish pre-feasibility studies. The secondary objective is to generate added value to the decision process associated with the pre-feasibility studies. This objective has been achieved by an innovative adaptation and application of cutting edge decision support systems to the pre-feasibility studies.

Project
Mobiling of Microstructure, Mechanical Properties and Structural Performance in Thin Walled Ductile Cast Iron
Ductile cast iron has good mechanical properties and low production cost and is therefore widely used as a construction material. Cast parts in ductile iron can however be improved further by optimisation with numerical modelling. This not only involves the casting process itself but also the subsequent mechanical performance during service. The casting process has a large influence on the finale mechanical properties and the numerical modelling of the solidification of ductile iron is therefore a key factor in the entire optimisation linking the process and the performance of the part. Solidification of ductile cast iron is very complex involving many different factors such as properties and chemistry of the melt and the heat flow from the casting into the mould. Concerning the heat flow an important factor is the thermal resistance between the casting and the mould, normally described by the heat transfer coefficient (HTC). The knowledge about the HTC is however very little, especially concerning thin walled castings. The aim of this project is to investigate the heat transfer from casting to mould experimental, with emphasis on the HTC. The results from the experimental work will be incorporated in an advanced numerical model of solidification of ductile cast. The output of the solidification simulation will be mechanical properties which can be used as input for the structural mechanical simulation of the casting part in the applied function.

Project

Modelling of Microstructure, Mechanical Properties and Structural Performance in Thin Walled Ductile Cast Iron
Ductile cast iron has good mechanical properties and low production cost and is therefore widely used as a construction material. Cast parts in ductile iron can however be improved further by optimisation with numerical modelling. This not only involves the casting process itself but also the subsequent mechanical performance during service. The casting process has a large influence on the finale mechanical properties and the numerical modelling of the solidification of ductile iron is therefore a key factor in the entire optimisation linking the process and the performance of the part. Solidification of ductile cast iron is very complex involving many different factors such as properties and chemistry of the melt and the heat flow from the casting into the mould. Concerning the heat flow an important factor is the thermal resistance between the casting and the mould, normally described by the heat transfer coefficient (HTC). The knowledge about the HTC is however very little, especially concerning thin walled castings. The aim of this project is to investigate the heat transfer from casting to mould experimental, with emphasis on the HTC. The results from the experimental work will be incorporated in an advanced numerical model of solidification of ductile cast. The output of the solidification simulation will be mechanical properties which can be used as input for the structural mechanical simulation of the casting part in the applied function.

A Coordinated Action towards the promotion and consolidation of all RTD activities for large-scale integration of DER in the electricity market
FP6

The integration of DER in the European electricity networks has attracted attention of energy producers, network operators, policy makers and R&D community. In some countries it created a number of challenges for the electricity supply system creating barriers for further expansion of DER. Furthermore, there exists a lack of awareness and understanding of the possible benefits and scope of DER in the electricity system, while environmental goals and security of supply issues ask for solutions that DER could give in the future. The SOLID-DER Coordination Action will tackle the barriers for further integration of DER, overcoming the lack of awareness and fragmentation in EU R&D results by consolidating all European DER research activities. In particular awareness of DER solutions and benefits will be raised in the new Member States, thereby addressing the specific issues and barriers faced here. Consequently the key objectives of the project are: Identify and assess the critical developments, innovations and findings in meeting the R&D needs for large-scale integration of DER. It concerns developments in the field of legislation, regulation, DER support policies, market access, technical breakthroughs in DER supply and enabling technologies. To provide an assessment of costs/benefits and concepts of business models for DER and pro-active networks. Raising awareness of benefits of DER and organising dissemination of knowledge and capacity building in the new MS. The assessment and recommendations of RTD activities and its progress on national, regional, and EU levels will be reviewed and commented by the representatives of the electricity business community. This intensive dialogue will lead to an effective achievement of the overall EU energy policy goals and optimising the penetration of DER.

Innovative Joining Processes Applying Integrated Modelling

Advanced industrial product development is faced with steadily growing demands for joining new materials, often in dissimilar combinations, implying complicated joining problems. It is therefore imperative that manufacturing of joints in high tech products should be treated with scientific engineering methods. This is, however, seldom done to an extent justified by its importance. Although traditional arc welding processes have been subjected to numerical analysis of isolated problems such as temperature analysis, weld pool dynamics, microstructural evolution as well as transient and residual stress/strain and distortion analysis the idea of modeling with the aim of optimizing the entire process is still in its infancy state, and when it comes to more sophisticated processes like resistance welding (RW) and friction stir welding (FSW) even more basic numerical studies are in an early stage of development. Both of these processes need complex thermo-mechanical calculations, microstructural predictions as well as thorough analysis of large plastic deformations in order to predict weld strength and optimum welding parameters as well as final geometry. These problems are challenging and of multi-physics nature involving complex mechanisms comprising several cross-disciplinary areas such as materials science, thermodynamics, solid and fluid mechanics as well as process technology and applied numerical analysis. The objective of the present project is to develop advanced numerical models applicable for simulation of RW and FSW aiming at possible optimization of the entire processes. Focus will be set on overall numerical modelling strategies specific for each of the two welding processes as well as more detailed investigations of microstructures, mechanical properties, strength and weld quality.

Kinetics of metal dusting corrosion of Fe-Ni-Cr(-Al) alloys

There is a pursuit for maximum efficiency in steam-reforming technologies in the petrochemical industry and a rising interest in the Fischer-Tropsch gas-to-liquid (GTL) hydrocarbon processing technologies. These require higher carbon content and lower water vapour content in the syngas (CO/H2-based gas atmospheres). Fe-based (steel) and Ni-based high chromium alloys are widely applied as high temperature materials in the petrochemical industry. In the temperature range 450-850 °C all Fe-based and Ni-based metals in high temperature process equipment that get into contact with carbon-bearing gases, like syngas, are subjected to carburization, i.e. dissolution of carbon in the alloy and the development of carbides. Generally, in the petrochemical industry and, particularly, in the reforming units, such carburization may lead to a very aggressive corrosion phenomenon known as metal dusting (MD), also called catastrophic carburizing. During MD the protective chromium (and aluminum) oxide layer on the Fe-based and Ni-based alloys is attacked locally. The stochastic nature of MD has hitherto hindered a thorough investigation of the parameters influencing the kinetics of the (catastrophic) carburizing process and, thus, targeted optimization of the alloys’ compositions.

Project

An important part of the cooperation within the IEA (International Energy Agency) is organised through national contributions to Implementation Agreements on energy technology and energy analyses. One of them is ETSAP (Energy Technology Systems Analysis Programme), started in 1976. Denmark has signed the agreement and contributed to some early annexes. This project is motivated by an invitation to participate in ETSAP Annex X, Global Energy Systems and Common Analyses: Climate friendly, Secure and Productive Energy Systems for the period 2005 to 2007. The main
activity is semi-annual workshops focusing on presentations of model analyses and use of the ETSAP tools (the MARKAL/TIMES family of models). The project was also planned to benefit from the ED project NEEDS -New Energy Externalities Developments for Sustainability. ETSAP is contributing to a part of NEEDS that develops the TIMES model for 29 European countries with assessment of future technologies. An additional project Monitoring and Evaluation of the RES directives: implementation in EU and policy recommendations for 2020 (RES2020) under Intelligent Energy Europe was added, as well as the Danish Centre for Energy, Environment and Health (CEEH), starting from January 2007.

Automated corrosion sensors as on-line real time process control tools

The project is based on need for small, simple, and inexpensive device for monitoring and evaluating corrosion. The information on actual corrosivity of the environment is crucial for effective corrosion protection. Long-term monitoring of the corrosivity can help in better understanding of fundamentals of corrosion processes, as well as in risk assessment. Basically the most innovative objectives of the project consist of (1) high sensitivity of the sensor device, i.e. short time to response; (2) miniature and independent character of the device, which can be placed virtually anywhere and monitor the aggressiveness of the environment in long run; (3) simple operation demanding no special knowledge of the personnel; (4) possibility of on-line monitoring of corrosion risks at distant places due to GSM reading. The project brings together three SMEs from France, Denmark and Czech republic. All of them are well established in their fields, i.e. metal galvanizing, electronics and software development, and corrosion monitoring in soils. However, none of the companies is able to activate required financial and human resources to develop the highly-innovative product as it includes research in several distant domains, extensive testing and characterization, and demanding market analysis and dissemination process. An important part of research and development will be carried out by the R&D partners. The project will help the SMEs to put together their knowledge and potential in their precisely defined areas of excellence. Metal sensors for the device will be produced in Czech republic, the electronics in France and the application and marketing will be provided by the Danish and French companies. The high level of transnational cooperation will improve competitiveness of all the SME partners. It is expected that this cooperation is going to continue in further projects. Corrosion rate of technically important metals and their alloys, as well as the character of the corrosion attack, depends largely on the properties of the environment. In atmospheric exposure conditions, temperature, relative humidity, concentration of contaminants such as chloride, sulfur dioxide, nitric compounds and others, precipitation and cyclic changes of the parameters affect the corrosion rate. In aqueous media, presence of other chemicals, flow rate, concentration of oxygen and other parameters affect it. In general, it is very difficult or even impossible to predict corrosion rate of metals with sufficient accuracy. Since the knowledge on the rate or form of corrosion process in potentially hazardous environment is necessary for safe and reliable operation of industrial facilities, protection of cultural heritage, transportation and other applications, it is desirable to collect and on-line evaluate data on the actual danger of corrosion damage. This information can be a part of decision-making processes leading to appropriate measures to minimize corrosion damage. In principle, there are wide range of methods for corrosion monitoring based either on physical or electrochemical principles. However, the monitoring techniques have often one or more of the following drawbacks: Long time to response (i.e. insufficient sensitivity), ambiguous response, non-universality, user-unfriendliness, big size, and high price. The aim of this project is to develop a small, independently-working sensor device for monitoring of corrosion. The sensor device can work independently or it can be controlled by a distant operator. To fulfill different material requirements, the sensor device will be developed with sensors from wider range of metals. The main principal areas of application of the sensor device are: industry, transportation, electronic equipment, and cultural heritage. It can be used for rapid identification of potentially dangerous conditions, for mapping of aggressiveness of environment, or as a device checking correct function of corrosion protection systems. The advantage is that no special knowledge is necessary for operating of the device. Moreover, since it can be operated from a distant place, data evaluation can be separated from data acquisition.

Project
Simultaneous Optimisation of Operating Costs and Passenger Service in Public Transit

In the Greater Copenhagen area approximately 200,000 hours are lost every day when passengers are waiting for a connecting bus or train. Hence, an enormous socio-economic potential lies within the development of new methods that can be used to generate timetables which have better temporal correspondences. Naturally, this can be achieved by assigning more resources to cover the timetables. However, the public transit companies are faced with administrative claims for cutting operating costs which renders improvements of the service intractable. Hence, efficient and near-optimal use of the resources is of paramount importance for the public transit companies.

The project addresses the multiple objective planning problem of generating timetables that on the one side is economically feasible for the transport companies and on the other hand also offers high-quality service to the passengers by minimising the unproductive time spent on waiting between one or more shifts.

Project: Training and Mentoring of Science Shops (TRAMS)

TRAMS will develop specific structural services for the International Science Shop Network Living Knowledge. In this way the co-ordination actions in TRAMS will contribute to the goals of the network. It will be an important step for the future funding of the network. The EC project ISSNET shows there is a growing request for tools and support to get started with new science shop activities in many regions of Europe. Therefore it is foreseen that the training and mentoring activities that will be developed in TRAMS will fulfil an expressed need, and provide a benefit for civil society. After the pilot activities and development of materials in TRAMS these tools for support will be made available for the members of the network at low costs. This will assure the future use of the deliverables of TRAMS. The preliminary results of ISSNET make clear within the network there is a demand for these activities. TRAMS is an indispensable milestone in the networking of science shops. Development of innovative practice in science shops will be encouraged, through a customised training programme toolbox and appropriate partnering and exchange (mentoring) among members of Living Knowledge. TRAMS will focus on both sides (users and suppliers) in training and mentoring, because both groups are important stakeholders in the project. This will allow the project to have a direct input on the needs for training and mentoring and on the available tools and expertise. The users in TRAMS are the pilot group of the mentoring and training activities. All members of Living Knowledge can participate in activities of TRAMS (e.g. workshops) and make use of the results and materials of TRAMS. The workpackages of TRAMS will focus on 1) Mentoring, 2) Training materials 3) E-
modules, 4) Dissemination of results. TRAMS will co-ordinate co-operation with the members of the International Science
Shop Network. It will build on the results and recommendations of previous EC projects.

Induction Assisted Welding Technologies in Steel Utilisation

Coming from automotive applications, high strength steel grades to be applied in lightweight construction are more and
more required in many industrial sectors as construction, agricultural machinery or shipbuilding industry. Beside this
weight saving aspects, demands like a high wear resistance combined with high toughness at a wide temperature range
are important for these applications. However, fundamental metallurgical facts cause these steels to be relatively difficult
to weld. As modern high strength steels are manufactured using more and more complex thermo mechanical treatment
techniques, a loss of the base material properties after welding is identified to be the core of these problems. Moreover,
these steel grades contain a relatively high amount of carbon that leads to significantly increased hardness and cold crack
occurrence caused by martensite formation in the weld. Future development of steels with even higher carbon content will
accentuate this problem. The existing limitations as insufficient fatigue strength can be overcome by the use of appropriate
welding methods as laser GMA hybrid welding combined with induction heating. Thus, an adaption of weld seam
properties to the base materials properties will be enabled. Benefits expected from the research: • Detailed, application-
related understanding of the interaction between induction and welding processes • Concrete knowledge about the
metallurgical and mechanical weld seam properties of induction assisted welded steel • Increased use of high strength
steels to gain benefit of both cost saving and raw material saving aspects Main goals of the project: • Enable an inceased
use of high strength steels for a number new industrial applications • Improvement of weld performance and reduction of
rework • Providing new induction assisted welding processes suitable for mass production

Innovation and Domestic Multinationals (DOMUS)

The overall aim of the DOMUS project is to study the role of large domestic multinationals (domus) in the national innovation system (NIS). By domus is meant firms with business units or firms in other countries but with headquarters in the relevant Nordic country. Domus play an important role as competence nodes and gravitation centres, and are of great importance for the innovative capabilities of customers and suppliers including SMEs and for competence development in knowledge institutions including cooperating institutes and universities. The aim is to map the effects such companies have on the overall capabilities of NIS. The project will also investigate the effects a multinational presence has on the home activities of domus. It is for example important to find out the key factors that influence the domus’ localisation decision of headquarter functions and other associated activities in the Nordic countries, and to what extent national ownership is of importance.

Project

Strategic Transport Management in the Øresund region

Strategic Transport Management in the Øresund region, STMØ, is a project conducted in co-operation between Malmö Högskola, Danmarks Tekniske Universitet, Københavns Handelshøjskole, Sjöfartsverket in Sweden, Yrkeshögskolan in Helsingborg, Øresund Logistics, Landskrona kommun, Øresundsuniversitetet, Malmö Stad, Københavns Kommune and Region Skåne. One aim of the project is to develop a new scientific field, rooted in the Øresund region, which will be able to deal with questions associated to the interaction between traffic related consequences and development of society. At the same time the project seeks to develop an interregional master education, located at Øresundsuniversitetet, which will provide students, business, organisations and authorities competences to make optimised and valid solutions for transport management. A reason for creating a new education is the business desire to save costs and increase competition on production, trade, logistic and transport and thereby optimise the production- and transport chains. Another main focus is to try to define the increasing need for transportation, due to global, regional and local development and describe how this can be combined with a fair development of society. Several areas of importance has been identified and grouped as economic-, legal-, structural-, functional-, environmental- and technical matters. These matters need to be discussed and integrated in order to define and overcome possible barriers for an optimised and valid transport development. Thus STMØ aims at analysing the specific education needs related to the above mentioned matters, and based on the analysis creating the master education of Strategic Transport Management in such a way that it will be compatible with other educations already located in the Øresund region.

Establishment of Nordic Laser Hybrid Welding Relationships
A very essential basis for future maintaining and improvement of the Scandinavian level of ‘living standards’ is a high employment rate in combination with the production and export of high value / high quality products / components. The proposed project clearly supports this situation by networking / promoting new technology for improving productivity and product quality into a traditional materials manufacturing industrial sector, comprising of a large number of SME companies. Advanced fully automated processes as e.g. laser hybrid welding will become an important player in this field in the future. The project is partly sponsored by Nordic Innovation Centre.

Atmospheric Composition Change: an European Network (ACCENT)

Changes in atmospheric composition directly affect many aspects of life, determining climate, air quality and atmospheric inputs to ecosystems. In turn, these changes affect the fundamental necessities for human existence: human health, food production, ecosystem health and water. Atmospheric composition change research is therefore fundamental for the future orientation of Europe's Sustainable Development strategy. The overall goals of ACCENT are to promote a common European strategy for research on atmospheric composition change, to develop and maintain durable means of communication and collaboration within the European scientific community, to facilitate this research and to optimise two-way interactions with policy-makers and the general public. ACCENT will establish Europe as an international leader in atmospheric composition change research, able to steer research agendas through its involvement in major international programmes. ACCENT furthermore aims to become the authoritative voice in Europe on issues dealing with atmospheric composition change and sustainability. The ACCENT joint research programme focuses on aerosols, biosphere-atmosphere interaction and transport and transformation of pollutants and it also looks for new partnership in economic and Earth System analysis. Integration will be achieved by creating common facilities and activities including: a dedicated interactive web portal, models, data-bases, measurement platforms, training and education opportunities, quality assurance procedures and facilities, integrated assessment and synthesis of scientific results and an interface with the general public. The excellence and the commitment of the ACCENT Partnership guarantee an effective and durable integration of the European atmospheric composition change research and that it becomes a pillar of the European Research Area. The activities the Science Shop at DTU is involved focus on *To set up a structural two-way interaction between ACCENT research and policy-making in Europe. *To create a platform for dialogue between ACCENT and the general public, including NGOs.
Reduced energy consumption for basis ventilation in heavy process industry
Many process industries use extensive, often over dimensioned, ventilation systems to provide a proper working environment. It is the aim of the project to develop methods to make ventilation systems that reduce the over-all need for ventilation so that the energy consumption for ventilation is kept at a minimum, while at the same time securing a sound working environment.

Micro electrochemical set up for local corrosion and electrochemical characterisation
High performance demand for several engineering alloys and components, and miniaturization of electronics and
development of MEMS requires better understanding of local corrosion characteristics frequently down to µm scale. This is
because in metallic materials corrosion is a sensitive function of microstructure, in particular the local electrochemical
activities of several microstructural heterogeneities such as second phase particles and grain boundaries. Corrosion of
microelectronics circuits and MEMs is also a recent problem, which demands measurement resolution down to few
microns as the components are extremely small, and measurement needs to be carried out without damaging the entire
component. These limitations can be overcome by the use of so called micro electrochemical technique, which in various
forms are being used by few investigators. A popular idea involves the use of a pipette connected to a system to control
the solution flow at the tip. Through addition of reference and counter electrodes, the pipette system becomes a
microscopic electrochemical cell, which can then be used with high precision to determine the electrochemical
characteristics of the microstructural region of interest. The resolution of the technique is determined by the size of the
pipette tip. Although this approach of measuring local electrochemical activity is attracting corrosion investigation, the
equipment is not available commercially. This project aims to develop such a micro electrochemical set up at the division
of Materials and process Technology at DTU.

Skin-pass rolling
Skin-pass rolling is the final forming step of the production of cold rolled steel sheet performed to avoid Lüder band
formation, ensure required tolerances and tailored surface texture. The process has quite different parameter settings than
conventional plate rolling due to small reductions (app. 1%), large contact length compared to the sheet thickness and
large roll radius compared to the contact length. Furthermore, skin-pass rolling is usually performed under dry friction
conditions, which lead to high friction between the material and the work rolls causing severe inhomogeneous
deformation. Skin-pass rolling has great influence on mechanical material properties and resulting dimensional tolerances
as well as resulting surface topography of the cold rolled sheets, which are tailored to meet stringent customer
requirements for subsequent sheet forming applications. In spite of the large influence on final properties the skin-pass
rolling process has not been subject to much fundamental research. The lecture describes a two years study on the
subject carried out at IPL-DTU together with Professor Niels Bay. By elasto-plastic FEM analysis skin-pass rolling has
been modelled showing the deformation to be highly inhomogeneous. An extended sticking region in the roll gap is
determined together with the boundary between the sticking and the sliding region, where heavy plastic deformation is concentrated in the surface. The location of the transition between the sticking and the sliding region is strongly influenced by the coefficient of friction. The influence of process parameters such as friction, reduction and texture of roll surface on the resulting texture of the rolled plate is shown quantitatively. The numerical predictions are shown to be in good accordance with experimental analysis.

Establishing SCC test facility with micro electrochemical attachment and in situ high resolution visualization system
In metallic materials, corrosion and stress corrosion is a sensitive function of microstructure, in particular the local electrochemical activities of several microstructural heterogeneities such as second phase particles and grain boundaries. The microstructural heterogeneities could act as a local corrosion site, which under stressed condition often develops into a stress corrosion crack. On the other hand in engineering components, structural heterogeneities of a higher scale could be produced by joining and processing techniques such as welding (eg. heat affected zone and nugget), cutting and
machining operations; all have tremendous influence on corrosion and stress corrosion. In all the above cases, in-situ visualization of local corrosion / stress corrosion process in solution using a high resolution video microscope system with a wide range of magnifying capability could provide significant information on how the various microstructural factors controlling the corrosion performance of engineering materials. A typical example is the in-situ visualization of initiation of stress corrosion cracks adjacent to intermetallic particles in aluminium alloys assisted by the local corrosion processes. This project aims to develop a SCC test facility attached with micro electrochemical set up for fine scale electrochemical measurements and a high resolution visualization system for viewing the corrosion/SCC in-situ.

Marie Curie Joint European transport Research network (JET)
The proposed network will arrange a series of seminars and Ph.D.-schools within transport modelling and optimisation. Members are – among others – TØI, SINTEF, MOLDE, Linköping, KTH, LTH, ITS Leeds, Imperial College London, ETH Zurich, IDSIA Lugano, Univ. of Rome, Reggio Calabria, Brescia, TUDelft, Eindhoven Tech. Univ., TRAIL, National Tech. Univ. of Athens, Univ. of Hamburg, RWTH Aachen. These are among the leading universities in transport within Europe. CTT is leading partner. The network is planned to be jointly chaired by Oli B.G. Madsen and Otto Anker Nielsen. Jeppe Husted Rich is project leader. Funds for application (JET) have been obtained from the national research foundation (STVF)

**Trans Tools**

TRANS-TOOLS aims to produce a European transport network model covering both passengers and freight, as well as intermodal transport, which overcomes the shortcomings of current European transport network models. Main shortcomings include the unsatisfactory representation of mix of traffic (short/long distance and freight/passenger), the (partly) missing presence of intermodality and freight logistics in models, differences in implementation of Origin-Destination base year for freight traffic in some models, outdated character of some models, no sufficient linkage of network based transport models with socio-economic effects and external effects. As on the European realm different models for different options and with different IPR settings are anticipated, it is useful to construct an IPR free instrument on the basis of the best available knowledge (i.e. notably at partners that have been involved in building models that involve European policy questions). The aim is to develop a European network-based transport model starting from the ideas consolidated in the modelling experience of the consortium partners. This means that some of the features of the current available EU models will be added, considering that while the model cannot be a tool for every purpose, the selection of the model features should be essentially on the basis of the policy needs addressed by the European Commission services. It is already quite clear that the SCENES model approach will provide good suggestions for the treatment of passenger transport and the interaction of local and long distance traffic, that the VACLAV transport network will be a suitable basis for the development of an efficient transport assignment model, that NEAC will provide the information for proper description of freight transport and that the SCENES model will constitute a reference for the treatment of intermodal transport, as well as SLAM for logistics. This will lead in the following clear innovations obtained form TRANS-TOOLS: •New set up of a demand/supply model; •Intermodality for passenger/freight (as National and European transport policies seek to promote intermodality through different measures); •Inclusion of intercontinental flows (mainly for freight), as some models do not cover this segment; •Full coverage of Central and Eastern Europe (Accession Countries and the countries at the borders of the enlarged European Union); •Integration of the new Member States at a level similar to those of EU 15; •Feedback infrastructure development economy (as the question of indirect effects in the economy and on network level is important, especially where investment has a substantial influence - notably for Accession Countries); •Logistics/freight chain explicitly included; •Coupling method with local traffic in order to address the effect of congestion on long-distance traffic; •The consortium provides access to all relevant experience concerning EU and national modelling; •A software approach is chosen which results in a software modelling tool on network level.

**In-process quality assurance of micro components**
Der skal udvikles måleprincipper og målemetoder til in-process kvalitetskontrol af mikrokomponenter. Måleprincipperne skal kunne håndtere 2½D og 3D mikrokomponenter og den forventede nøjagtighed skal ligge i størrelsesordenen 3 - 5 μm. Der vil primært blive arbejdet med optiske løsninger, men integration af mekaniske og optiske løsninger kan blive nødvendige for at opnå den forødelde nøjagtighed i 3D. Der vil blive fokuseret på etablering af sporbarhed i kvalitetsstyringen.

User Supportive Embedded Configuration

Configuration is the technical term for the problem of selecting values for a set of parameters. The purpose of configuration is typically to setup digital equipment to behave according to user requirements or to specify needs in a software system. Common examples of configuration situations from everyday life is setting up the video-recorder at home or setting up the alarm system at work. In commerce, configuration arises for instance in tailoring a product to a customer's needs such as a PC, or in tailoring a service such as a travel. In industry, the configuration problems are even more complex than what most consumers' experience. Modern industrial equipment is facing configuration tasks with hundreds of parameters. Today's business software has thousands of parameters that influence its behaviour. The situation is that configuration is an omnipresent problem in many disguises. The goal of this project is to look beneath the disguises and contribute in three areas: to develop user interfaces suited for solving configuration tasks, to develop methods for describing product models, and to develop the basic algorithms needed for constructing configuration software that supports users in performing intuitive and error-free configurations. The three areas will be addressed by research in user-centred design, product modelling, and configuration technology. The project will focus on embedded configuration, where knowledge and rules about how a product may be configured is embedded in the product itself. Traditionally the specification of valid product configurations has been separated from the products themselves and the process of transferring knowledge about valid setup and installation from product specialists to other functions in a company, partners and end-users has been costly, error prone and time consuming. Embedded configuration eliminates the information gap between product specialists and other users of the product. Embedded configuration is to be based on a product model that captures the relevant knowledge about the product. The product model is made operational in the product as a guidance tool using a generic configuration engine and thereby turning the complex problem of configuration into an integral part of the product and the value obtained by it. In order to ensure that the guidance of the user interface is supportive in the configuration process, an approach based on analyzing the user's work processes must be taken.

**Job Quality in Europe/Denmark**

The Russell Sage Foundation develops and supports a cross-national comparison of the quality of low-wage employment in Europe and the United States. Having completed an extensive series of case studies of such jobs in the US in partnership with the Rockefeller Foundation, Russell Sage now seeks to commission a collection of comparable case studies for five European countries: Denmark, Germany, France, the Netherlands, and the United Kingdom. The stated aims of the overall project are to compare the quality of low-wage employment in the US with that found in Western Europe, with particular emphasis on how the wages and work conditions of low-paid employees are affected by employer responses to growing competitive pressures. Since firms in each country operate in distinctively different institutional environments, the comparisons should increase our understanding of how institutional variation affects the strategies adopted by firms in respect of work organisation, use of new technologies, wage structures, recruitment, training, career development, subcontracting, outsourcing and product/service innovation. The project concentrates on the following industries: Hotels, Retail, Hospitals, Food processing and call centers. DTU is responsible for the call center part of the research.

Ethical Traceability and Informed Choice in Food Ethical Issues
The main objective of the project is to develop the concept of ethical traceability as the basis for food buyers’ informed choice. By including philosophical and sociological researchers both theoretical and empirical aspects of ethical traceability and informed choice are investigated. The philosophical studies examine the two concepts in the light of selected philosophical theories and discussions, whereas the sociological case studies focus on the current use of traceability in the food chain and the actors’ attitudes to ethical traceability and informed choice.

Foreign Takeovers
The project will focus upon some impacts of increasing internationalization on regional innovation capabilities in the Nordic countries. How and to what extent foreign takeovers of Nordic firms affect local innovation capabilities as well as how policy makers in the Nordic countries approach this issue. By doing so the project intends to provide Nordic policy makers with a better knowledge base for policy formulation. The project consists of three sub-studies organized as modules: 1) Mapping of Multinational Corporations activity in the Nordic countries, 2) Case studies: impacts of foreign takeovers on local capabilities with software and pharmaceuticals as cases and effects on R&D, knowledge base and learning and innovation bases. 3) Policy study: policy responses to the impact of foreign takeovers on local innovation capabilities.

IMPRESS, STVF research consortium
The main scientific objective of the project is to develop a concept for the use of integrated modelling of manufacturing of cast and welded parts for the purpose of optimisation already in the design phase. This will involve a coupling of thermodynamic, process and structural and performance analyses as well as an inves-tigation of the possibility to use also standard optimisation tools in the process. The objective will be applying in-house software developed at the department as well as commercial codes. New models will be developed where needed with the emphasis on making the concept of integrated modelling a usable tool for an overall optimisation involving both the manufacturing of the part and the performance of the part during service. A valuable output of the project will be a better understanding of the influence of the evolution of the metallic structure during casting and welding (including fluid flow, solidification and stress/strain) in the post process stages, and how this should be taken into account in a structured and efficient way in a numerical code. The technological objectives are aimed at a more efficient exploitation of the material by supplying realistic me-chanical characteristics both in the design phase and in post exposure performance analysis. Efficiency of design and performance analysis, achieved by means of the use of optimisation techniques, will in turn sup-ply strong reductions on testing time, lead-time to market and costs for the industries and end users.

**kinetics of self-annealing in nanocrystalline electrodeposits**
Electrochemical deposition has become the key technology in manufacturing functional thin films with finite structures, e.g. for microsystems and microcomponents. The functionality and reliability of such films depend on their microstructure – however, the thermodynamically non-equilibrium state of as-deposited films causes substantial changes of the microstructure and related properties with time. For copper, which has become the dominant material for interconnects, dramatic microstructure changes due to recovery, recrystallization and grain coarsening have been observed even at room temperature (self-annealing). Electrodeposited nickel, a promising material to realize movable structures for micro-
electro-mechanical (MEMS) applications, is well-known for changes of the internal structure at elevated temperatures. The project will focus on the (self-)annealing behavior of free-standing electrodeposited Cu- and Ni-line patterns. In-situ XRD studies of crystallographic texture and peak analysis with simultaneous monitoring of the electrical resistivity on Cu-line patterns will be supplemented by FEGSEM-EBSD. Ni-line patterns will be investigated similarly with XRD and EBSD after annealing at elevated temperatures. From in-situ synchrotron measurements during isothermal annealing the growth rates of individual grains will be determined. Based on the gathered data (recrystallized volume fraction, grain size distribution, microstrains, texture components) deviations from the processes in deformed bulk metals will be modeled in order to account for the effect of surface, interface and grain boundary energies on the driving force of (self-)annealing in nanocrystalline electrodeposited films.

Project
The global call centre industry project: A global benchmarking survey
This project is a large comparative international research project on the quality of jobs and labor market outcomes for low wage service workers in several countries. It focuses specifically on workers in the rapidly growing call center industry, where labor markets that were once local and protected now face global competition. The dramatic growth of call centers in the last two decades is an important labor market phenomenon for low wage service workers. Whereas historically, service interactions were largely personalized and local, advanced information systems and rapidly declining costs of telecommunications have made possible the creation of geographically remote call centers in which transactions are mediated through telephone and computer technologies. This change represents a profound restructuring of labor markets for service and sales workers. Labor markets that were historically local and protected from trade are now exposed to national and even global competition.

Project

Product configuration in the construction sector
The primary objective of this project is to increase the productivity and quality of the Danish building industry by the application of product configuration to support a number of different processes in the building industry. In collaboration with a number of manufacturers of products for the building industry electronic models of their respective building components will be constructed. Based on the product programme of the companies involved the models will be constructed with a view to achieving two objectives: The first objective is directed towards the outside, towards projecting architects and performing contractors. Thus, architects are to be able to apply the electronic models directly during the execution of their architecture projects, both for sketching, visualization, and projecting. The contractors are to be able to use the models in connection with pricing and different kinds of simulation: construction and logistics, etc. The second objective is directed towards the inside, towards the internal procedures of the manufacturing firms. Here, the purpose is to enhance the efficiency of and rationalize the procedures in connection with the elaboration of the production basis, list of parts, pricing and quotations. In order to achieve the above objectives the electronic models will be made parametric and configurable, meaning that the models are constructed as “intelligent” electronic building components in which are encoded the engineer expert knowledge of the manufacturing firms. If, for example, a parametric and configurable model of a concrete staircase is elaborated, the computer will, after the encoding/entering of various parameters (width of
The research project is primarily based on the know-how of the Technical University of Denmark within the area of configuration of product models (contact person: Associate Professor Lars Hvam) and of the Aarhus School of Architecture within the area of parametric building components.

**ESTIAnet**

A significant part of the consultation activities in a number of important areas, including human resource development, IT-development, strategic planning and development and communication with other firms, is carried out by women consultants in small companies. Many of these women consultants have worked previously for several years in academia. However many women consultants do not receive the recognition or success that their efforts merit for a number of reasons, including exclusion from male ('old school tie') and information networks, resulting in lack of information about what is required for success on the national and European markets. Women and girls have always had less access to technology education than boys and men and this continues to be true for information technology. Consequently a high proportion of women consultants are unaware of either the capabilities and opportunities afforded by information technology or the risks to organisations that fail to make use of it. These factors hold throughout Europe to a certain extent, but they are particularly relevant to women in the candidate EU countries of the CEEC and CIS. On the positive side research results on the prerequisites for success are now available from studies carried out in a number of countries. Access to these research results and the opportunity for women consultants to interact and network with women researchers and each other would be of great benefit to both consultants and researchers. The women consultants would gain invaluable information with a resultant increase in both material and intangible rewards, whereas the women researchers would gain additional insight into the problems facing women consultants. The aim of this project is the development of a Web-based observatory and consulting center which would analyse the prerequisites for success in different European countries, with the analysis to include the effects of culture, different economic systems, histories and other specifically national factors on success, and gender differences in approaches and attitudes to success. The project would involve existing networks from higher education and the comparative analysis and integration of existing research results. All project outputs would be available in several different European languages to make them accessible to women consultants across Europe. In addition project outputs would be produced in a variety of media to make them accessible to disabled women consultants and researchers. Integrated data bases of research results will be set up and made available on the web, as well as on CD and in hard copy. All web sites will be fully accessible both to disabled consultants and researchers and women with older software and hardware. Discussion forums will be established, both on the web and on a rotating basis in several different countries across Europe. The availability of these two types of discussion forums will enable the participation of more women researchers and consultants and also have the advantages of facilitating direct contact between women researchers and consultants. Results from the face-to-face discussion forums will also be published on the web.

**Metal release by corrosion and wear in food industry**  
The objectives of this project are to identify the sources of metal contamination from stainless steel equipment in food industry, analyse the impact of the contamination and finally to suggest solutions for the problem. Metal release can cause a health risk for consumers with nickel allergy and the acquisition of data on metal content in not only raw products but also in manufactured food and ready-to-eat dishes will be an improvement of the present status. The obtained data on food products will be analysed and compared with challenge doses and estimated daily intake. By materials selection and development of more wear and corrosion resistant surfaces the general food quality can be improved, metal release reduced and longer lifetime of process equipment obtained – all leading to better products. So by technological solutions safe and high quality food production can be made possible.

New Concept of Industrial Welding and Cutting

If the technology functions as expected it will have a great potential. At best, it should be able to revolutionize industrial welding and thermal cutting. It has a theoretical potential to obtain unseen cutting speeds in both thin plates as well as thick steel plates. It should also be possible to obtain welding qualities and production capacities, which clearly surpass what can be realized today in practical welding production. The process will be competitive to the known technologies both in investment costs as well as operating costs.

Development of Supply Networks
The purpose of this project is to develop a systematic approach for the development and analysis of supply chains. The basis for this is an identification and definition of generic elements and structures in order to establish a taxonomy of supply chains architectures. Furthermore, it is the aim to define performance measures for supply chains and to identify relationships between structures and performances (both efficiency and effectiveness). The supply chain will be seen in a strategic context, including technological, organisational and inter-organisational aspects with special focus on new structures enabled by the possibilities of new ICT and new ways of organising the interplay between enterprises.
Improving International Science Shop Network (ISSNET)

The general objective of the thematic network 'Improving Science Shop Networking' (ISSNET) is to give citizens around Europe better access to scientific information and expertise. The demand-driven approach of science shops contributes to this objective and offers citizens a tool to contribute in the science and society debate. Sharing the expertise of existing science shops and support for the development of new science shops by improving the networking of science shops will advance citizens' participation in the dialogue between science and society. An international science shop network will be an instrument to link or initiate local or regional initiatives. In this way it will advance the outreach, size and impact of the contribution of science shops to citizens’ access to scientific information, knowledge and expertise. Activities of ISSNET contribute to the start, set up, and maintenance of an international science shop network. ISSNET will also develop collaborative relationships with science shop-like institutions and networks inside and outside of Europe.

Material problems in waste incinerators
Investigation of the effect of microstructures in Ni-base weld overlays on corrosion of water walls in waste incinerators.

Department of Management Engineering
**Metal Release by Corrosion and Wear in the Food Industry**

The objectives of this project are to identify the sources of metal contamination from stainless steel equipment in the food industry, analyse the impact of the contamination and finally to suggest solutions for the problem. Metal release can cause a health risk for consumers with nickel allergy and the acquisition of data on metal content in not only raw products but also in manufactured food and ready-to-eat dishes will be an improvement of the present status. The role of the National Food Institute is to analyse trace elements in processed raw materials and foodstuffs sampled at various sites along the process line in the food industry. The trace element content is determined by Inductively Coupled Plasma Mass Spectrometry (ICPMS) equipped with a collision/reaction cell for interference reduction/removal. The obtained data on food products will be analysed and the health risk evaluated by comparison with the estimated daily intake. By materials selection and development of more wear and corrosion resistant surfaces the general food quality can be improved, metal release reduced and longer lifetime of process equipment obtained – all leading to better products. So by technological solutions safe and high quality food production can be made possible.

**Product specification systems: Economics, Technology and Organisation**

Product specification systems: Economics, Technology and Organisation (ProSSETO) The project was started the 1st of February 2003 and is funded by the Danish Technical Research Council (http://www.forsk.dk/eng/stvf/index.htm), the project ends the 31st December 2004. The Danish Technical Research Council has generously donated 2 million DKK covering four man-years plus expenses. It is the purpose of the project to develop knowledge about the use of product specification systems perceived as a combination of technical, economic, and organisational factors. The project has put forth the hypothesis that interplay between these three factors is crucial for realizing benefits from implementing product specification systems with regard to technical functionality, competitiveness and work environment. The project will further shed light on the radical organisational changes resulting from implementing a product specification system. The research is conducted by a team of 6 researchers with experience and competence in the areas of economics, organisation and the technical aspects of product specification systems. The project is headed by Associate Professor Lars Hvam email: lhv@ipl.dtu.dk whom together with Assistant Professor Jesper Riis, email jri@ipl.dtu.dk represents the technical perspective. The Economic perspective is contributed by Associate Professor Jørgen Lindgaard Pedersen, email: jlp@ipl.dtu.dk and Assistant Professor Kasper Edwards, email: ke@ipl.dtu.dk. The organisational perspective is provided by Associate Professor Niels Møller, email nm@ipl.dtu.dk and Research Assistant Morten Møldrup, email: mmd@ipl.dtu.dk.

Call Centre- development of work

The Danish research project: “Development of competences and work organization in call centres” – also named “Call centres – development of work” www.callcentres.dk (2003-2005). The project is an intervention project – a combination of research and change - in collaboration with four Danish companies (Danske Bank, TDC, Nykredit og Sydsjællands Elselskab) and carried out in six call centres with 800 employees. The idea is to develop competencies and work organization in order to better working conditions and the quality of service. The first half of 2003 has been dedicated to research and dialogue: A survey covering all 800 employees, case studies and dialogues with managers and employees of perspectives and possibilities of positive changes. Now (2003 autumn) the change-plans I the different call centres have been decided and the changes will start up in October 2003). Niels Møller is leader of the project. The project is supported with 15,5 million Danish crowns (2 mio euro) from The European Social Fund and with a support from the companies up to 30 million. The project has already builded its own network and relations to other networks in the Danish call centre industry. The EU project “Call centres – development of work” consists of four researchers at DTU and CASA and a group of consultants from Handelsskolen Sjælland Syd. The project has a reference group (see www.callcentre.dk) representing a broad range of interest (labour marked organization, public services and institutions).

CIRP inter-laboratory comparison of coordinate measurements using an

An interlaboratory comparison on mechanical and optical coordinate measuring machines (CMMs) was organized by the Centre for Geometrical Metrology (CGM), Department of Manufacturing Engineering and Management (IPL), Technical University of Denmark (DTU) and carried out within Collège International pour l'Etude Scientifique des Techniques de Production Mécanique (CIRP). The project was carried out in the period from August 2002 to November 2004. In the project, 15 research laboratories were involved from 9 countries: Belgium, Denmark, Germany, Italy, Poland, Spain, Switzerland, United Kingdom, USA. A total of 23 CMMs (12 mechanical and 11 optical) were used to measure an optomechanical hole plate designed and manufactured by DTU. A measurement procedure was sent to each participant together with a plate to be measured. The measurement procedure refers to the German DKD guideline, using the reversal method with traceability achieved by a comparator measurement. Using the optomechanical hole plate, the measurement procedure can be carried out on optical as well as mechanical measuring machines. Circulation started in March 2003, and was completed in September 2003, whit three optomechanical hole plates being circulated at the same time. A smooth and timely circulation was obtained. The measuring procedure was reported by all participants to be followed without problems. A report was produced for each participant where the results of the single participant are analysed and compared with the reference values provided by CGM, using mechanical calibration according to the DKD
guideline. An expanded uncertainty $U = 1.2 \mu m$ was used by CGM. The reference values were verified after circulation within the measuring uncertainty. The optomechanical hole plate has proven to be a suitable artefact for both mechanical and optical CMM measurements. The construction of the plates has shown a good stability through the approx. 6 month circulation, even though the plates have been measured mechanically, using touch probes. Only a problem was experienced: some holes on a plate showed a calibration difference of about one micrometer after circulation. This is probably due to some sensitivity of the plate to clamping, which otherwise has not been a problem. This observation has led to an additional instruction following the plate of not using clamps. From the results from the comparison, it can be expected that the optomechanical hole plates can be calibrated using the DKD procedure with an uncertainty in the range between 0.5 $\mu m$ and 2 $\mu m$. Using the hole plate, it is possible to compare the performance of measurements obtained using optical and mechanical CMMs. Optical CMM measurements can be divided in two groups. A group leading to deviations larger than 2 $\mu m$, and a group with deviations that are comparable to those using mechanical machines. All but one laboratory could perform reversal measurements. Transfer of traceability was established as follows: 8 using gauge blocks, 2 laser interferometers, 1 zerodur hole plate, 2 callipers, and 1 quartz standard. Out of the 23 measurement campaigns, 5 optical and 2 mechanical machines were not provided with establishment of traceability. The optomechanical hole plate is a suitable reference artefact providing traceability of CMMs, in particular optical CMMs which seem to lack available artefacts. A comparison of measurements in a single plate position shows agreement with reference values within the reference uncertainty. This comparison shows that optical measurements, generally speaking, can be as good as mechanical ones.

Global Network on Energy for Sustainable Development (facilitated by UNEP)
The Global Network on Energy for Sustainable Development (GNESD) facilitated by UNEP is a south-south knowledge network, set up as a type II intervention after the World Summit of Sustainable Development (WSSD). The GNESD Secretariat is hosted at the UNEP Risoe Centre, DTU, with 10 member centres located in three continents (Africa, Asia and Latin America): AFREPREN/FWD (Kenya), ENDA (Senegal), ERC (South Africa), MEDREC (Tunisia), TERI (India), AIT (Thailand), ERI (China), Bariloche Foundation (Argentina), CENBIO/UFRJ (Brazil) and the Mario Molina Centre (Mexico).
The objective of GNESD is to promote energy access in developing countries and to establish synergetic opportunities between energy access and development. It does this by undertaking scientific research and providing practical policies that help governments and intergovernmental organizations to further mutually inclusive energy access and development activities. Though GNESD is global, its member partners operate locally at national and regional levels.

IDEAL: Integrated Development Routes for Optimised Cast Aluminium Components
A recently carried out Leonardo EC Project (COPROFOUND) has demonstrated that it is really fundamental to create a reliable link among metallurgy, foundry practice, numerical methods, and information technology. The integration of these fields and proper managing of the software-derived information will make the process simulation of casting processes not only a simple “solver” of particular and small-size problems, which have a relatively small impact on the production economy, but also a fundamental tool for understanding and solving the majority of problems generated during the production of cast components. So, the main technical objective is the integration of numerical codes performing simulation of the casting process (with prediction of the microstructural and mechanical behaviour of cast alloys), optimisation of the manufacturing cycle and structural analysis (including the analysis of crash behaviour of cast components). Up to now, during the design stage of a component, its mechanical properties have been regarded as constants. In the reality, all properties of cast products change due to the different microstructural features produced by different cooling rates achievable (consider, e.g., the effects induced by different wall thickness) and to the defects such as porosity, oxides, strongly affecting the performances. Furthermore, residual stresses arising from the stages of manufacturing processes are often not included in the calculations, today, due to the difficulties of getting a reliable estimate. The first target is therefore to get a reliable forecasting of the mechanical characteristics directly from casting simulation. Then this information will be transferred as input to structural analysis codes that may so consider a quite realistic material instead of calculating the usual ideal one. A better knowledge of the microstructure (resulting from processing) vs. mechanical properties correlations will help a more correct definition, also inside National and International Standards, of the characteristic properties of casting alloys, which, actually, are given “for guidance only”, without really supporting the engineering design. Conventional heat treatment and innovative treatment technologies, such as Liquid Hot Isostatic Pressing (LHIP) are strongly growing their role in Aluminium Foundry: their potential will be also considered and implemented into the integrated numerical code. The development of an optimisation module working under an integrated approach with simulation code will allow a fast set up of the most suitable casting parameters and will help to have minor amount of defects inside the component as an added value to feasibility. Virtual optimisation of the process will reduce to the minimum the expensive and time consuming “test and trial” iterations to a minimum. Foundry men experience will never be neglected, but such a tool can substantially support the decisions to be taken at a work shop level.

Numerical Modelling of Laser Beam welding of Aluminium Alloy-Steel Joints
A significant trend is noticed in automotive industry towards a wider use of aluminium and aluminium alloys (AA). They have great specific strength and a high corrosion resistance allowing the design of lightweight constructions with excellent mechanical properties. In this context, the demand for laser welding of the material combination of aluminium alloys with steel (AA/St) has increased. However, laser beam welding (LBW) desired for longer AA/St joints or more complex joints (e.g. car door/hinge or multiple sheet structures in car bodies) is still difficult on account of the formation of extreme brittle compounds at the intermetallic interface. Controlling and predicting this formation is at present very difficult due to the current lack of understanding of the involved solidification and transport phenomena in the weld pool. The aim of the project is the development of a numerical model of deep penetration laser beam welding of the material combination steel/aluminium alloys. It will allow the prediction of: thermal cycle in fusion zone and intermetallic interface-formation of intermetallic phase (brittle compounds AlxFey) shape of the seamA completely new approach will be applied to evaluate the solidification phenomena at the interface phase between the aluminium and steel part considering the complex multi-phase heat transfer problem and the fluid flow of a binary mixture. The basis of the algorithm will be a finite volume discretisation of the conservation equations of energy, mass and momentum, of the minimisation of surface energy and of the thermo-metallurgical phenomena. The extreme fine spatial discretisation necessary to resolve the intermetallic layer will be realised employing a composite grid technique. Although the project has a focus on the industrial aspect, the main content of the project is fundamental research at high scientific level. The development of the model describing the physics of the complex non-linear problem and of an efficient numerical algorithm for the underlying large-scale discretisation is the main task of the project. Considering the complexity of the problem, it cannot be expected to reach the development of a complete industrial simulation tool within the two years frame of the project. But it is expected that the improvement of the understanding of the phenomena will make a sound foundation for such a development.

Young people's choices in relation to engineering education and engineering jobs

Young people’s choices in relation to engineering education and engineering jobs. Objektive The aim of the project is to investigate the impact of work/life balance on young people’s choice of education, job, and career in the field of engineering. Research has shown that especially young women fear that a job and career as an engineer cannot be combined with their hope of a good family life. The philosophy of the project The project will describe young people’s notions of their (possible future) work as engineers, and develop their visions of a good working life and a good family life. On the basis of concrete visions of work and family, the dilemmas between the two spheres will be worked out. Other factors will be investigated too, e.g. job content and salary. “Young people” are defined as men and women at different stages in life, which (eventually) lead to engineering jobs. The target groups are: High school students Engineering students Young masters of engineering Young masters of engineering with newly established families The design of this study is based on a hypothesis that young people make their choice of education, job, and career without much knowledge or (especially) any concrete ideas of their own wishes for the future. Therefore a survey on their attitudes is less interesting. Methodology Groups of 15 persons will be selected from the four target groups. The individual group will be rather homogenous in relation to age and life experiences. The groups will represent various life-experiences and therefore various conditions for making choices. At the same time, the four groups simulate the process of one person going through his or her life-stages. In total, eight groups will be formed on the base of the young people's willingness to participate. Future workshops (one day/twice) and group discussions will be conducted in each group, in order to: • Investigate young people's notions and expectations of their (possible) future working life and family life. • Develop their visions of a good working life and their vision of a good family life. The visions should be made concrete. • Discuss practicable good balances between work visions and family visions, and also the dilemmas and conflicts between the two. • Discuss the impact of the balance between work visions and family visions in relation to future and present choices of education, job, and career.
Promoting the occupational health services' efforts in relation to technological changes in enterprises

Part II of research project studying the effort of the occupational health service (OHS) in relation to technological changes in enterprises. Part II focus on OHS as creators of learning processes in client enterprises, and on knowledge management in the OHS unit.

ENLUB Development of new, environmentally acceptable lubricants, tribological tests and models for European sheet forming industry

Objective: The European sheet forming industries are facing considerable problems due to legal requirements of introducing environmentally acceptable lubricants as substitutes for the present hazardous/toxic ones. The objectives of this project are to develop new environmentally acceptable lubricants and an approach for prediction or prevention of lubricant film breakdown in sheet forming operations to facilitate a shift in the European industry towards environmentally acceptable lubricants. These objectives will be achieved by developing new environmentally acceptable lubricants based on pine oils and dry-film polymers, a system of experimental tests for sheet forming tribology combined with numerical modelling of lubricant film breakdown, which are integrated into a design support system. The expected output are new lubricants and a combined experimental and theoretical approach for prediction or prevention of lubricant film breakdown.

Micro/Nano Manufacturing
Within the last few years we have seen a growing tendency that many of the products are getting smaller and smaller.
This is the case for products which we use both privately and in industry. This miniaturization is often characterized by a strong integration of micro mechanics and micro electronics. It is a continuously increasing challenge to create the operational basis for an industrial production of microtechnological products. As the products through product development processes are made applicable to a large number of customers, the pressure in regard to developing production technologies that make it possible to produce the products at a reasonable price and in large numbers is growing. These two demands further point at the use of metal, polymers and ceramics (or combinations of these) as materials to be used for microtechnological components and products. In the light of this development IPL has established a cross-disciplinary research programme with the purpose of creating an industrial production basis for microtechnological products/components through technology and product development. Thus the discipline of Micro/Nano Manufacturing at IPL can be defined as the activities that enable an industrial production of components within the dimensional scale of micrometers and nanometers. The components themselves may be of these dimensions, but also larger components with functional characteristics within the micrometer/nanometer area are included as an essential part of the activities. The driving force of the development is miniaturization. IPL will primarily focus on industrial production of components in metal, polymers and ceramics.

**Interaction between liberalised energy markets**

The linkages between the power, natural gas and district heat sectors are examined and the consequences of the liberalisation are analysed. The changes in incentives for different players in energy market are described and especially integration of natural gas distribution and CHP production is analysed with respect to regulatory challenges and possible welfare impacts. The project also deals with bundling of energy commodities and the potential threat to small customers from such bundling practises.

Project
Modelling Material Flow in manufacturing Processes with Eulerian Methods

The aim of the project is to develop new, more accurate and much faster numerical algorithms for the simulation of metal flow in processes involving metal forming. This will be carried out in the framework of 3-D Finite Volume (FV) formulation. It is expected that this new formulation will reduce the necessary CPU-time dramatically compared to the traditional Finite Element (FE) methods. These are often in 3-D analysis of metal forming accompanied by very large CPU-times due to remeshing in which the FE-mesh distorts together with the geometry while attempting to follow the deformation of the solid material (Lagrangian formulation). Moreover, the accuracy of the FE-solution can be severely damaged by distorted elements. It is the idea of the project to overcome these problems by applying a 3-D finite volume formulation based on a
Eulerian approach where the mesh is fixed and the metal flows through it. The FV method based on a Eulerian formulation is common practice for material flow simulations in a wide range of processes, e.g. mould filling in casting, melt pool modelling in welding and droplet atomisation in spray forming. Metal forming processes typically involves large material flow as well. The proposed Eulerian Finite Volume method is particularly suited for simulating the large material deformations appearing in metal forming operations, and at the same time eliminates the need for volume remeshing techniques, commonly considered the main bottleneck in 3-D forming simulations based on Lagrangian FE formulations. Due the difficulties outlined, 3-D forming simulation based on the conventional FE technology is still not being readily implemented in the metal forming industry, and application and translation of 3-D simulation results into forging practice have shown very little success while 2-D analysis today is commonly applied in industry. Considering the complexity of the problem it is by no means expected to reach the development of a complete industrial simulation tool within the four years frame of the project, but it is expected that a sound foundation for such a development will be made.

New Superconductors: mechanisms, processes and products
Since discovery of the first high temperature superconductors in 1986 large activity has been noticed as regards R&D on superconducting materials and manufacturing of superconducting tape, which can transmit extremely high current compared to conventional conductors. These tapes are applied for winding of powerful electromagnets for hospital scanning and levitated trains, coils for energy storage, and power cables for electricity supply. IPL has worked together with NST (Nordic Superconductor Technologies) since 1997 on development and optimisation of the numerous mechnical
processes (drawing and rolling operations) involved in manufacturing of BSCCO/Ag based superconducting tape. The present project concerns mechanical processing of new superconductor materials such as MgB2, which in 1991 was discovered to have superconducting properties. The project is part of a framework programme financed by the Danish Technical Research Council, in which IPL-DTU collaborates with ELTEK-DTU, Risø National Laboratory, NBI-Copenhagen University and Danfysik.

LCA-center Denmark
LCA Center Denmark is a knowledge centre for life cycle assessments (LCA) and the life cycle approach. The centre promotes product-orientated environmental strategies in private and public companies by assisting them in implementing life cycle thinking. LCA Center Denmark is partly funded by the Danish Environmental Protection Agency and is managed by Institute for Product Development(IPU), COWI and dk-TEKNIK ENERGY & ENVIRONMENT. The aims of LCA Center Denmark are: * To assist companies that have a need for environmental assessment of products in a life cycle perspective. * To secure that the development of tools and methods for the life cycle approach in Denmark builds on a solid and scientific basis. * To promote product-orientated environmental work in companies (Life Cycle Assessments and other Environmental Management Systems). * To maintain the existing cooperation between Danish LCA stakeholders.

Prevention of Accidents in Small Enterprises
The objective of the project is to develop preventive methods tailored to small enterprises. The basic understanding is that accidents in small enterprises are rare events, and the learning experience is limited. But stories about near misses and risky situations are much more frequent. The project is implemented in cooperation with an occupational health service, and another important objective is to fit the methods to the available resources in the service.

Gas-Assisted Injection Moulding of one and multi-component parts

Gas-assisted injection moulding (GAIM) is a two-component process, where a mould is filled partly with a polymer melt (a thermoplastic material), followed by the injection of inert gas into the core of the polymer melt. Parts produced by gas-assisted injection moulding are hollow. Consequently they use fewer resources than solid parts produced by conventional
injection moulding. Complex parts consisting of both thick and thin sections can be produced (unlike in conventional injection moulding) with lower material usage, lower machine investment, better surface finish (better quality) and shorter cycle (production) times, compared to conventional injection moulding. In this project it is the intention to develop two well-monitored equipments. One, allowing the experimental investigation of the gas-polymer displacement process, developing the internal surface in a product. The other equipment, based on a simple compression moulding technique, should allow the investigation of the replication of the mould surface in the plastic, incorporating an insert with well-defined microstructures in the mould. The equipments should be prepared for later multi component displacement investigations, where more than one polymer is displaced simultaneously. It is the major target of this Ph.D. project to gain a more thorough understanding of the underlying physical processes responsible for the formation of the inner and outer surface in a plastic product. In order to gain understanding of the polymer melt distribution in the GAIM process, we have to resort to a numerical model of the process. Modelling of the GAIM process, with respect to the real fluid behaviour of the polymer melt (polymer melts are highly complex fluids), even in a simple geometry have not yet been resolved. A more detailed understanding of flow properties and the influence of material parameters, e.g. the rheology is needed. It is the purpose to model the combined flow of a gas and a highly viscous polymer melt and the filling of the microstructures in the mould surface numerically, with the Finite Element Method, to obtain an understanding of both filling processes.

Social shaping of local environmental activities

Local environmental initiatives are analysed with respect to their social shaping and their impact on the capacity for handling environmental aspects. The project covers projects in South Africa and Denmark and have links to similar projects with focus on Thailand.
Ecological economics - a new perspective?
The field environment and economics has developed fast during the last twenty years. Neoclassical environmental economics has been dominant, but other currents have manifested themselves, e.g. ecological economics that has been institutionalized in associations and journals. The project aims at contributing to the assessment of ecological economics: Is the field crystallizing as a special perspective in the field of environment and economics, and if this is the case, how can the perspective then be characterized.

IT mgt
The purpose of this project is to establish administrative procedures for supporting all aspects of using IT-applications in an educational institution.

Centre for Logistics and Freight Transport
The Centre for Logistics and Freight Transport (CLG) is a multi-disciplinary research centre on logistics and freight transport. The Centre is headed by CTT. CLG is a cooperation between a number of Danish and international universities and companies. CLG is funded by The Danish Technical Research Council (STVF). The objective of the Centre is to strengthen the Danish research on logistics and transport. This is achieved through specific research projects and through networking activities within the center. A number of the research projects are multi-disciplinary. The scope of the Centre is to obtain an increased knowledge about the various stakeholders within the logistics and transport sector and to develop new methods and concepts which are applicable to the stakeholders. This includes organisatorial and management concepts as well as methods based on mathematical models in order to support the various stakeholders which briefly can be characterized as follows: Manufacturers and consumers of goods (transport users). Transporters (operators, forwarders, etc.). Transport infrastructure owner (public authorities, ports, airports, etc.). Public authorities (political means and control). National economics (derivated effects of the transport system and the external influences).

EUROMET.L-S11 comparison on surface texture
The measurement of roughness of technical surfaces is important in research and for industry. There are a lot of 2D roughness parameters that are defined and standardized by ISO. Calibration standards can be used to calibrate the instruments and ensure traceability to the SI unit of length. Most of those used are traced back to SI by national metrology institutes (NMI), which should participate in international comparison to proof the validation of measurement results. Sixteen NMI from the EUROMET region carried out measurements on standards between May 2001 and March 2003. The set of standards used complied with ISO 5436-1 and consisted of one depth-setting standard of type A, three calibration standards of type C, three standards of type D1 and one standard of type D2. The participants aimed to measure 50 surface roughness parameters. These included the most interesting parameters in the field of surface texture, i.e. Pt, D, Ra, Rz, Rmax, RSm and Rk. Additionally, for the first time, a comparison using software gauges of type F1 that complied with ISO 5436-2 was made, taking into consideration the fact that they have an important effect on the results obtained. A considerable number of the over 600 measurement results did not fulfil the En <1 criterion. Some of the problems are related to the determination of the depth of grooves on the depth-setting standard. This was really not expected at the beginning of the comparison. Other problems are related to more complex parameters like RSm and Rk and their ambiguous definition in the written standards. The final report has been peer-reviewed and approved for publication by EUROMET, according to the provisions of the Mutual Recognition Arrangement (MRA).

Motivation and Burnout. A case study on the relationship of human motivation and burnout in human service work

Networking Nordic Laser Materials Processing Knowledge
The objective of the project is to create a web-based platform in which it is able to gather all relevant information related to laser materials processing in order to stimulate Nordic research collaboration as well as to provide a platform for the Nordic industry for receiving quick and efficient information on the topic. Further, it creates a good basis for efficient communication between the mentioned parties. Information covers all technical aspects related to laser materials processing as well as being an integrated technological ‘market place’ for discussions, promoting seminars and conferences etc. Also
Promoting the occupational health services' efforts in relation to technological changes in enterprises

The occupational health service (OHS) in Denmark is only sparsely involved as adviser when technological changes take place in client enterprises. In order to promote the OHS efforts in this area, the work of OHS consultants has been studied in four cases of technological change. Instead of the two-dimensional expert – process consultant role we suggest a supplementary third role, the 'political reflective navigator'. This role is suggested based on evidence from the cases and concepts from actor-network theory on technological development.

Modelling Distortions of Large, Thinwalled Light Alloy Castings

The aim of the project is to develop and test new, innovative and fast numerical techniques for modelling thermomechanically induced distortions in large, complex light alloy parts. The goals are: Speeding up algorithms with an order of magnitude compared to conventional techniques, making it possible to simulate the manufacturing process of large complex parts at realistic computational times for industrial applications. Selecting and testing proper constitutive laws for prediction of distortions in light metal alloys, e.g. viscoplastic models. Testing various convergence criteria to ensure sufficiently accurate results for the analysis of macroscopic distortions Comparing different simulation techniques to recommend the most promising for commercialisation.

ISOPS, Industriel stansning og pladeformgivning – smøremekanismer, smøremidler og miljøaspekter
Punching and stamping of stainless steel is characterised as tribologically difficult due to galling caused by the brittle oxides and the large affinity of the base material to pick-up on the tool surface resulting in scoring of subsequently passing work piece surface. Until recently, the only lubricants able to impede galling in severe deep drawing, stretch forming and ironing operations were chlorinated paraffin oils, which are expected to be abandoned in near future due to environmental problems. In a national Danish research programme, 1994-99, two new lubricant systems have been developed as substitutes to chlorinated paraffin oils. Testing of these environmentally harmless lubricants under controlled laboratory conditions has shown very promising results and so has initial industrial tests at Danfoss, Grundfos and Volvo among others. In the present research programme "Industrial punching/blanking and sheet metal forming – lubricants, mechanisms of lubrication and environmental aspects" running from 2000-2003 the development and testing of lubrication systems will be further studied in a co-operative project between Institut for Kemi, DTU, Institut for Produktion, DTU (in the following named IPT), Danfoss, Grundfos, RM Rich. Müller, Esti Chem and Houghton Danmark. Objectives The objective of the present project is to develop a general methodology for determination of the limits of lubrication in sheet metal forming of stainless steel. Furthermore development and testing of tailor-made surface topographies improving the resistance to lubricant film breakdown will be studied.

Value of time in traffic models
Life Cycle Assessment on the hydraulic motor OMV/OMVW-800.

The project was made under the supervision of Sauer-Danfoss (formal host of this project) and the Department of Manufacturing Engineering and Management (Institut for Produktion og Ledelse IPL) at Denmark's Technical University (DTU). The aim of the project was to perform a cradle-to-grave Life Cycle Assessment (LCA) on the Hydraulic motor type OMV/W-800 manufactured by the international company, Sauer-Danfoss. The goal of the study was to clarify the impact potentials, including resource consumptions and environmental impact potentials throughout the entire lifespan of the hydraulic motor OMV/W-800 by means of a literature survey, Sauer-Danfoss literature and data, and other information sources by adopting the LCA methodology as a tool. Furthermore the goal was to carry out a complete quantitative analysis on the product’s processes and materials, and identifying and evaluating the most promising options for improving the product systems with respect to environmental quality and resource efficiency. Many of Sauer Danfoss A/S suppliers did not want to disclose data on their production due to fear of competition and confidential agreements with third party suppliers. Even with the knowledge of my confidentiality agreement with Sauer-Danfoss A/S, many of the suppliers and company employees were unwilling to cooperate with me. Thus the data collection proved to be very time consuming. Especially data on ancillary substances, proved to be hard to acquire. Therefore the main conclusions are drawn on incomplete data with regard to toxicity impacts. The goal and scope of the study is defined in detail. Data collected in the inventory part is a mixture of actual measurements, calculations, literature data and estimates. To accomplish the goal, the potential impacts on the environment and the resource consumptions of the hydraulic product system are assessed by means of a literature survey and the EDIP computer tool. Based on the results from the EDIP PC Tool, it is determined that the main impacts of the hydraulic product system are the contributions to persistent toxicity, human toxicity, ecotoxicity, global warming, acidification, photochemical ozone formation and nutrient enrichment and material related resource consumptions of nickel and molybdenum are due to the use of raw materials in the form of high quality steel. Finally, the service and efficiency of the hydraulic motor are found to be significant parameters.

**INDUBRAZE, Induction brazing of complex material combinations and induction hardening**

*Project*

INDUBRAZE In the project a combined numerical and experimental methodology for fast determination of appropriate coil geometry and position in induction brazing tube-to-plate joints of different ratios between tube and plate thickness and different combinations of the materials stainless steel, brass and copper, have been developed. An appropriate coil design and an approximate positioning are determined by numerical analysis. Required heating time, power and optimum position of the coil, are subsequently found experimentally by measuring the temperature development during heating using thermocouples mounted on both sides of the joint.

EasyTrac
The present dimensional calibration methods are highly diversified/specific and require a big number of different standards. All these standards must be calibrated in accredited laboratories which from the side of logistic effort, availability of the standards, and costs for the calibrations is a big burden for small metrology service providers. With coordinate measuring machines accuracies can be reached which satisfy almost any regular demand from industrial metrology - if the proper procedures are used. The problem is the knowledge of the procedures and the official acknowledgement of them. The intention is to significantly reduce in average the efforts and costs associated with the traceability of industrial dimensional metrology laboratories by the almost exclusive use of coordinate measuring machines (CMMs). Fully documented, ready to use procedures shall be developed. The procedures shall cover virtually the whole spectrum of calibrations required for dimensional metrology in classical mechanical production, excluding for the time being only the calibration of small gauge blocks and small standards for form (i.e. roundness, straightness, cylindricity).

CIAMM - Center for Industrialised Application of Mathematical Modelling

CIAMM started its activity in late 1999. The goal has been to develop planning tools based on mathematical modelling, which can be used in everyday planning and replanning in larger companies. The planning problems are usually so complex, that a human planner cannot take into account all possible solutions. During the three project years the main case study has been the steel plate storage at Odense Steel Shipyard. The storage consists of 250 stacks containing more than 3000 types of steel plates. The plates are lifted by two gantry cranes sharing tracks and hence unable to pass each other. When a specific plate is needed in the production, all plates above this in the stack has to be moved to get access to the plate. Hence each plate is lifted unproductively a number of times before it is actually removed from the storage. The problem addressed is how to organize the storage in order to minimize the number of superfluous lifts. The project has developed methods both for planning the daily sequences of lifts and for and on-line dispatch strategy for operating the cranes. Saving of 50 - 60% on the current practice has been achieved. In addition, a packing system has been developed based on a real-life case from Bang & Olufsen, in which boxed are packed into containers taking into account also constraints regarding loads on the items and support of these. Finally, a methodology for IT-system development with a large optimization content has been developed and described - the technique resembles the DSDM method, and much attention is given to rapid prototype developments and to knowledge exchange between end users and developers, since this has turned out to be a major obstacle in the development process.

**GLOBEMEN**

*Why?* - The project is initialised in order to define and harmonise ICT support requirements in various one-of-a-kind industries operating in various cultural environments. By combining the views and requirements of various industries, GLOBEMEN aims to guide and encourage the industry and IT vendors to develop and adopt improved IT infrastructures. The project aims to demonstrate functionalities which offer attractive market opportunities to IT vendors for product development to satisfy the needs of various industries world-wide.

*What?* - The objectives are: to define a reference architecture for virtual manufacturing enterprises, to implement proof of concept industrial prototypes, to demonstrate core features of the architecture, and to promote deployment by IT vendors, manufacturing industry, academia and standardisation.

*How?* - The approach of GLOBEMEN is to address three main aspects of manufacturing: sales and services, inter-enterprise management and engineering. Based on industrial requirements specifications the work will be co-ordinated and integrated into an IT architecture for enterprise networks and virtual enterprises. This will include a reference model and associated methodology or guidelines, based on which IT support for such virtual enterprise networks can be set up and operated.

*For whom?* - The models and architecture will be generic enough so as to be usable in all one-of-a-kind industries, directly usable by standards bodies and by IT vendors. The results will be validated through industrial prototypes, and implemented in selected applications. The results will be consolidated and disseminated to the industry, standardisation bodies and IT vendors.

*Time & cost?* - The duration of GLOBEMEN is 3 years (Jan 2000 - Mar 2003). The estimated effort is 1000 person-months.

Ultrasound actuator for aerospace applications
Aiming primarily at aerospace applications, principles of designing a spherical ultrasound motor are being investigated. The motivation for ultrasound motors in aerospace applications is the possibility to make a non-magnetic, lightweight and high precision torque device for control applications. The research project aims in particular at investigating the contact modelling effects, which play a major role for developed torque and efficiency of the motor.

CEVI method development
The project aimed at developing operational methods for savings and reuse of water and waterborne energy and chemicals in industrial wet processing. Methods include simple pinch analyses for targeting water savings and -reuse as well as methods for system design of water reuse systems. Moreover procedures for identifying options for process optimisation were developed including savings of water, energy, and chemicals. Finally, the feasibility of separation technologies such as membrane filtration and evaporation was revealed through laboratory and pilot scale test procedures. Solutions of large savings and short economic pay-back periods were chosen and successfully implemented in full scale.

The impact of science shops on curricula and research
The impact of science shops on university curricula and research has been analysed through a questionnaire and case studies among some university based European and American science shops. The project was part of a project carried out by an international network of science shops doing research on different models for science shops, societal and organisational factors that have an impact on the success and failure of science shops, training needs in science shops, the impact on curricula and research and the possibilities for strengthening the international networking through a more formalised network, an international database and an international journal.

**Precision farming**  
This project analyses the impact of precision farming (PF) practices in Denmark by using technology assessment methods. The project involves an integrated application of participatory impact analysis and cost-benefit analysis of various PF-practices in cereals. Precision farming implies that the use of nutrients, lime and pesticides are used site-specifically according to the site-specific needs on the field by using the GPS-system for positioning on the field. The decision support systems for conducting site-specific application is based on soil maps, yield maps, information about nitrogen-status (with remote sensing) and weed maps (weed detection).

**The Parallel Building Project (Parallelbyggesagen)**  
This development project is a result of the report 'Øresund - en region bliver til' (Öresund - the rise of a region), published by the Swedish and Danish government in May 99. This report states that 'parallel building projects should be executed by private clients on the Danish and Swedish side of the Sound, in order to identify specific barriers to the building industry, and furthermore to generate improvements in the basic conditions for integration in the region'. Thus, a prime goal is to make records of the barriers encountered by an actor from one country operating on the other side of the Sound. As a secondary purpose this project should encourage networking and integration between universities and research institutions involved in the planned monitoring process, attached to each building project. Results will be organised on a database, accessible for SME's and other actors interested in construction in the region.

Numerical Modelling of Residual Stresses in Spray Forming

The aim project the project is to describe residual stresses in spray forming with respect to predicting the formation of cracks and the distortion of the preform. The mathematical description of the temperatures in the deposit will be developed on the basis of a 2-D cylindrical (r,z) finite volume model. The interface between the atomization and the deposition models will be based on a new approach of local droplet distributions at the surface of the preform combined with models for sticking efficiency. Based on the calculated temperature and geometry of the spray formed material a 2-D cylindrical (r,z) finite volume model for the stresses and the deformations will be developed as well.

Project
Experimental investigation in turning as a basis for modeling chip formation, tool life and cutting fluid performance.
Results from the project will be valuable on two levels: they will provide accurate experimental data to be fed into the modeling of the process; they will build the documentation for attaining those data in following well defined procedures, thus preparing the bases for future development of accredited testing in metal cutting. In addition, new formulations of environmentally friendly cutting oils will be tested against commercial reference products obtained from mineral oil basestock.

Powercut
The present project entails research with the goal to extend laser cutting of steel based metals to thickness above 20 mm and laser powers in the 6-12 kW range, with adequate accuracy and economically viable cutting speeds. It is an objective to establish an overall understanding of the combination of gas flow, laser radiation and material flow in the laser cutting process, and on the basis of the results from these studies to make the relevant decisions concerning the design of a mirror system, cutting head and nozzles. Through the theoretical description of the mechanisms of cut front forming with its many aspects the outcome should give input to dimensioning of mirror optics and cutting nozzles.

Distributional impacts of energy and environmental taxation
This project is an empirical analysis of the economic consequences of energy and environmental taxation for various population groups in Denmark. Micro data for household expenditure and types of energy are combined with information on income, size of household, occupational status, age etc. to analyse the burden that environmental taxes pose to different income groups etc. The general conclusion is that energy taxes are regressive with the exception of taxes on petrol.

**PRECEPT: Process Reengineering in Europe: Choice, People and Technology**

The overall objective of this project is to investigate the choices surrounding the Business Process Re-Engineering (BPR) concepts and their appropriateness in different national, industrial etc. contexts and to explore the different opportunities for developing socially feasible and acceptable BPR-oriented concepts, in order to contribute to the development of a European model for long term sustainable economic development. The project directly addresses new models of work organisation and the use of IT, and their implications for organisational performance and competitiveness - through its substantive focus on the choices of methods and concepts for business process redesign. It further addresses the means by which ideas about good practice for the business use of technologies and techniques are generated and disseminated. The project will examine the different approaches to BPR that have been espoused, and how they have been taken up differently by various exponents in different national, regional and sector contexts.

Thematic Network Microbiologically Influenced Corrosion of Industrial Materials

The purpose of this network is to bring together scientists and engineers from European industries, research organisations and universities to promote scientific and technological co-operation in order to better understand microbiologically-influenced corrosion (MIC), sometimes termed biocorrosion, phenomena, to assess its' risk, and to propose effective ways of its' mitigation. The multidisciplinary character of the project requires promoting effective communication between all the different partners involved in the network. Communication is organised according to three main areas: 1.Enhancement of the relations between academic teams with different backgrounds (biochemistry, microbiology, electrochemistry, and materials) is necessary to improve the fundamental understanding of microbiologically-induced degradation and/or corrosion. 2.Exchanges between engineers from different industrial sectors are strongly encouraged. Each of them possesses a particular know-how for MiC prevention in different application domains. Their techniques gain efficiency if they exchange their different experiences. 3.To create multiple links between academic teams and R&D industrial groups. This provides the academic investigators with new specific MiC cases, on practical applications and at industrial scale. On the other hand, the connection with academic researchers helps the industrial partners to organise their own approach concerning fundamental well-identified topics and to define more efficient strategies against MiC. In order to be efficient, this network is planned over four (4) years and the numbers of partners have been limited to 24. The industrial areas have been chosen carefully where significant synergies seemed possible (i.e. medical industry is also affected by MiC processes, but has not been involved in this network). Eleven (11) universities or research organisations, and eleven (11) industries are the present partners. The partnership will be open to two (2) other partners from other EC member states, during the network operation. The network is organised into six (6) tasks. Two tasks are linked to the fundamental research areas of biofilms (Task 1) and Corrosion (Task 2). Three tasks are devoted to specific application projects, such as MiC risk assessment (Task 3), MiC mitigation (Task 4) and biofilm and corrosion monitoring (Task 5). One task is devoted to personnel exchanges (Task 6). Task 1 (Biofilms) started to collect and to homogenise methods of assessing MiC. A workshop was devoted to this purpose and personnel exchanges started to transfer knowledge between the different laboratories. Future work will provide answers from questions arising within the other task groups, concentrate on homogenising MiC assessment methods and to increase knowledge of MiC mechanisms, such as investigating the role of...
enzymes in the MIC process. Task 2 (Corrosion) performed a survey over field and laboratory experiences with different materials. The data collected is currently in the process of analysis to find means of identifying MIC. Furthermore, an analysis of the electrochemical behaviour of material in different systems will be performed. Task 3 (MIC risk assessment) chose “Emergency and cooling water systems” for a risk assessment model. A list of MIC relevant aspects has been drafted and exchanges with the tasks 1, 2, 4 and 5 will help to identify possible parameters for the development of the model. The influences of each identified aspect of MIC on the overall process will be estimated, so that a likelihood of risks table can be developed. Task 4 (MIC-Mitigation) drafted a state-of-the-art summary about methods currently used in industry and their performance and economical aspects. It is planned to develop guidelines for MIC diagnostics (with Task 3 and 5) and guidelines on general system design and materials. Task 5 (Biofilm and corrosion monitoring) provided a state-of-the-art overview of monitoring devices. The different devices and systems will be tested and evaluated to provide an estimation of the economical benefit of the new technologies. Task 6 (Personnel Exchange) is investigating into the possibilities of effective dissemination of the results to persons outside the network, such as the organisation an summer school.

Project
**Evaluation of Green Action Plan, Denmark**

Evaluations of the Danish part of the International Campaign Green Action Plan (Grøn Livsstil). 'Grøn Livsstil' aims at qualifying and supporting individuals and families to take action in order to change their households towards sustainability. The evaluation focused on qualitative aspects such as: the potential of change of the initiatives the development of the campaign, and the strategies and organisation of the Danish campaign. The evaluation comprised of large number of qualitative interview and collects important knowledge of organising local processes of change.

The project is realised in collaboration with Prima Industrie in Italy and Optis in France. The objective of the project is to develop and validate technology for integrated, modular, high power laser systems for thick section cutting (up to 20 mm) of complex 2D and 3D parts. Beside of this, innovative sensors and control systems are being developed for detecting and controlling anomalies in the laser cutting process as well as the position and size of a CO2 laser beam.

Center for hygienic design
The project Hygienic Design is a co-operation between the Technical University, research institutes and partners from the food processing and biochemical industry. Biofilm formation is a major concern in food processing industry. It is aimed to improve surface material hygienic lifetime by selecting surface materials in combination with cleaning chemicals and cleaning procedures. Department of Manufacturing Engineering and Management is involved in development of materials with low bioadhesion (resistance towards biofilm formation), designed on the basis of effect of surface structure, surface chemistry, and cleaning properties. The work also includes development of quantitative techniques for examination of bioadhesion as well as corrosion. Studies have been made of the effect of surface finish of stainless steel 316 on adhesion of bacteria in stagnant media and under flow as well as field tests.

Neural process optimization of pulse plating in the electronic industry

The purpose of the project is to optimize the pulse plating process using mathematical models. The traditional electronic industry uses a chemical bath with additives to make the through-hole plating on printed circuit boards. The pulse plating process can make the through plating without the additives and even improve the quality of the copper. So there is both solution to an environmental problem and a quality problem. Based on the measurements from plated printed circuit boards, the mathematical model is used to find the optimal pulse parameters. In this project, there is used artificial neural nets to solve the problem. With the final model, it should be possible to "feed" the neural net with a CAD-design. Based on the design and the "knowledge" of the neural net, it will be possible to compute the optimal pulse parameters.

Environmental Management and Health & Safety in Construction

This project has as its purpose to present a state-of-the-art within management of the external environment and of health & safety in construction. The research is based on studies of literature and including recent examples of management practises in connection with large construction works. The results of the project are to be presented in a textbook aimed for teachers in engineering educational institutions as well as for their students.

Evaluation of regulation for flexibility – a methodology
Period: 12 Sep 2017
Daniel Møller Sneum (Guest lecturer)
Department of Management Engineering
Systems Analysis

Description
Regulatory changes for increased flexibility in the energy system entail socio-economic consequences, which must be evaluated in addition to the consequences for flexibility, to provide a comprehensive analysis of the impacts. This study proposes a methodology for such evaluation of regulation.

Transferring knowledge from building operation to design - A literature review

Period: 11 Sep 2017
Helle Lohmann Rasmussen (Speaker)
Department of Management Engineering

Description
In this paper we propose a new use of Machine Learning together with Mathematical Optimization. We investigate the question of whether a machine, trained on a large number of optimized solutions, can accurately estimate the value of the optimized solution for new instances. We focus on instances of a specific problem, namely, the offshore wind farm layout optimization problem. In this problem an offshore site is given, together with the wind statistics and the characteristics of the turbines that need to be built. The optimization wants to determine the optimal allocation of turbines to maximize the park power production, taking the mutual interference between turbines into account. Mixed Integer Programming models and other state-of-the-art optimization techniques, have been developed to solve this problem. Starting with a dataset of 2000+ optimized layouts found by the optimizer, we used supervised learning to estimate the production of new wind parks. Our results show that Machine Learning is able to well estimate the optimal value of offshore wind farm layout problems.

Tramp ship routing and scheduling with voyage separation requirements
Period: 17 Jul 2017
Jesper Larsen (Guest lecturer)
Charlotte Vilhelmsen (Other)
Richard Martin Lusby (Other)
Department of Management Engineering
Management Science
Transport DTU
Operations Research

Description
This presentation addresses a tramp routing and scheduling problem. Tramp ships operate like taxies by following the available demand, as opposed to liner ships that operate like busses on a fixed route network according to a published timetable. Tramp operators determine some of the demand in advance by ensuring long-term contracts. The rest of the demand comes from optional voyages found in the spot market. Routing and scheduling a tramp feet to best utilize feet capacity according to the current demand is therefore an ongoing and complicated problem. We add further complexity by incorporating voyage separation requirements that enforce a minimum time spread between some voyages. We developed a new and exact Branch-and-Price procedure for this problem. A dynamic programming algorithm generates columns, while a novel time window branching scheme is used to enforce the voyage separation requirements.
Computational results show that the algorithm finds optimal solutions very quickly for the vast majority of test instances. We compare the results with two earlier published methods and show that our Branch-and-Price approach outperforms both an a priori path generation method and an Adaptive Large Neighbourhood Search heuristic.

Teaching Assistant for course 15.872 System Dynamics II
Period: 15 Apr 2017 → 2 Jun 2017
Daniel Alberto Sepúlveda Estay (Guest lecturer)
Bradley Morrison (Lecturer)
Department of Management Engineering
Management Science
Transport DTU

Description
15.871 and 872 introduce you to system dynamics modeling for the analysis of business policy and strategy. You will learn to visualize a business organization in terms of the structures and policies that create dynamics and regulate performance. System dynamics allows us to create ‘microworlds,’ management flight simulators where space and time can be compressed, slowed, and stopped so we can experience the long-term side effects of decisions, systematically explore new strategies, and develop our understanding of complex systems. In these system dynamics courses we use simulation models, case studies, and management flight simulators to develop principles of policy design for successful management of complex strategies. Case studies of successful strategy design and implementation using system dynamics will be stressed. We consider the use of systems thinking to promote effective organizational learning. The principal purpose of modeling is to improve our understanding of the ways in which an organization’s performance is related to its internal structure and operating policies as well as those of customers, competitors, suppliers, and other stakeholders.

During the course students use several simulation models to explore such strategic issues as fluctuating sales, production and earnings; market growth and stagnation; the diffusion of new technologies; the use and reliability of forecasts; the rationality of business decision making; and applications in health care, energy policy, environmental sustainability, and other topics.

Students learn to recognize and deal with situations where policy interventions are likely to be delayed, diluted, or defeated by unanticipated reactions and side effects. You will have a chance to use state of the art software for computer simulation and gaming. Assignments give hands-on experience in developing and testing computer simulation models in diverse settings.

Description
MIT STAMP/STPA Workshop took place during March 27-30, 2017.

STAMP is an accident causality model based on systems theory and systems thinking. STAMP integrates into engineering analysis the causal factors in our increasingly complex systems such as software, human-decision making and human factors, new technology, social and organizational design, and safety culture.

STPA is a powerful new hazard analysis technique based on STAMP while CAST is the equivalent for accident/incident analysis. These tools are now used globally in almost every industry. Newer tools, such of those for doing early concept analysis (STECA) security analysis (STPA-Sec) and leading indicators have been developed. This free workshop will provide attendees with the opportunity to learn how to use these new tools, to meet with users and to hear about applications, evaluations, and the latest developments in this powerful new approach to system safety engineering and to cyber security.

Flexibility-Enabling Contracts in electricity markets
Period: 21 Mar 2017
Luis Rafael Boscán Flores (Speaker)
Department of Management Engineering
Systems Analysis

Description
We investigate the problem of incentivising flexibility in electricity markets. As the share of intermittent renewable energy increases in the generation mix, power systems are exposed to greater levels of uncertainty and risk, which requires planners, policy and business decision makers to incentivise flexibility, that is: their adaptability to unforeseen variations in generation and demand. The greater need for flexibility, along with the fact that its provision is costly, highlights the importance of efficient procurement. As a commodity, flexibility has multiple attributes such as capacity, ramp rate, duration and lead time among which there are complementarities. Additionally, along with traditional sources, which already enable flexibility, a number of business models, such as thermostat-based demand response, aggregators and
small storage providers, are emerging in electricity markets and expected to constitute important sources of flexibility in future decentralised power systems. However, due to presence of high transaction costs, relative to the size of resource, the emerging small resources cannot directly participate in an organised electricity market and/or compete. Therefore we ask the fundamental question of how should the provision of flexibility, as a multi-dimensional commodity, be incentivised in this context? We model the procurement of flexibility services from emerging small resources through bilateral contracts in a multidimensional adverse selection setting. We take a normative perspective and show how efficient contracts for flexibility services can be designed given its peculiarity as an economic commodity. Through a simulation analysis we elucidate the applicability of the proposed model and demonstrate the way it can be utilised in, for example, a thermostat based demand response programme.

Webinar: Recovery of Operations from Cyberattacks - a structure for response
Period: 15 Mar 2017
Daniel Alberto Sepúlveda Estay (Speaker)
Department of Management Engineering
Management Science
Transport DTU

Description
Cyber attacks on supply chains are a constant threat to organizations. News media are regularly reporting cyber attacks to supply chains that result in data theft or denial of service. Examples abound, such as the theft of credit card data for 70 million customers from Target in 2013, and a sophisticated distributed attack that blocked the websites of major companies in the east-US such as Amazon, Starbucks and PayPal, during most the 21st of October 2016. Although relevant, this coverage often overshadows cyber-attacks that affect supply chain operations, which continue to occur without media attention. This is giving hackers free range to refine and practice their techniques for increased penetration and damage, resulting in a whole different range of disruptions such as container theft, intervention of plant operation, or misallocation of payments, for example. The MIT Center for Transportation & Logistics (CTL) will host a webinar to address hacker-related vulnerabilities in supply chain operations. At the root of this problem lies the structure of data exchanges between supply chain partners. Key questions for supply chain managers include: How does your supply chain manage these data exchanges? How much are you assigning these problems to IT even though they have direct impact on operations? How does your supply chain prevent these attacks, or react when these attacks happen? Is your supply chain merely relying on external insurance, or do you understand how these exchanges can be designed and controlled in cases of attack for improved recovery? Dr. Jim Rice and Daniel Sepulveda, PhD student, will address these questions, and talk about research findings that offer a deeper understanding of the structures that supply chains can use to improve their response from hacker attacks so as to minimize operational disruption and allow a more efficient recovery.

Chairman: James Blanley Rice. Center for Transportation and Logistics at the Massachusetts Institute of Technology

Key questions for supply chain managers include: How does your supply chain manage these data exchanges? How much are you assigning these problems to IT even though they have direct impact on operations? How does your supply chain prevent these attacks, or react when these attacks happen? Is your supply chain merely relying on external insurance, or do you understand how these exchanges can be designed and controlled in cases of attack for improved recovery? Dr. Jim Rice and Daniel Sepulveda, PhD student, will address these questions, and talk about research findings that offer a deeper understanding of the structures that supply chains can use to improve their response from hacker attacks so as to minimize operational disruption and allow a more efficient recovery.)

35th International Conference on the System Dynamics Society (Event)
Period: 1 Mar 2017 → 30 Apr 2017
Daniel Alberto Sepúlveda Estay (Reviewer)
Department of Management Engineering
Management Science
Description
2017 marks the 60th anniversary of the founding of the field of System Dynamics. It is thus fitting that we hold the 60th anniversary conference in Cambridge, next to the MIT campus where Jay Forrester developed the field. Today, System Dynamics is used around the world, from K-12 classrooms through doctoral programs, in scholarly research across many disciplines, and in applications from organizational change to climate change, from medicine to management. We will celebrate the accomplishments of the past six decades and explore future directions by showcasing the best work in dynamic modeling being done today.

There will be plenary presentations showcasing important work in the field, along with parallel and poster sessions, making available the most current research, applications, and work in progress. There is a full day of skill-building workshops covering a range of topics from basic software use to advanced analysis techniques. In addition, there will be interest group sessions, student colloquia, the modeling assistance workshop, vendor displays, demonstrations, and more. The conference schedule will provide time for social and professional interaction.

The Society's annual international conference is held alternately in North America and Europe, with occasional appearances in Asia and the Pacific Rim. These conferences, and the meetings of local chapters and interest groups, introduce newcomers to the field, keep practitioners aware of current developments, and provide unparalleled networking opportunities

**Description**  
Engineering Systems Design - International Research Seminar at DTU  
  
Filippo Salustri (Ryerson University, Canada): "Three Monsters in design research: defining, formalizing, and visualizing - an overview of 3 very difficult problems that still task us" Despite tremendous headway in developing a robust science of design, some aspects of "designing" remain beyond our grasp, especially insofar as those aspects overlap significantly with non-engineering design disciplines. This talk will review some of Fil Salustri's efforts to clarify three of these aspects.  
  
Michael Kokkolaras (McGill, Canada): "Rigorous practical optimization for simulation-based engineering design" Computational models have accelerated the engineering design optimization process. Simulation-related challenges have been mostly addressed by heuristics-based methods. This talk presents alternatives that are supported by convergence properties.  
  
Georges Fadel (Clemson University, United States of America): "Evolving Designs using Affordances" The talk focusses on the adaptation of the theory of "affordances" from the field of perceptual psychology to better capture the perceived positive and negative interactions between the user and the artifact and use optimization to evolve designs.

**Innovation System Foresight**  
Period: 12 Jan 2017  
Per Dannemand Andersen (Speaker)  
Technology and Innovation Management  
Department of Management Engineering  

**Description**  
For several decades foresight has been a field of practice providing decision support for science, technology and innovation (STI) policy. Only recently has foresight begun to emerge as an academic field with contributions and contributors from many different traditional academic disciplines. The seminar will focus on the foundations of innovation system foresight, the practical challenges related to conducting innovation system foresight, and its possible policy implications. Professor Per Dannemand Andersen will draw on recent cases such as North Sea offshore wind services. He will also explore the difficulties scholars face when striving to contribute to both the academic development of the field and to STI policy practice.

Teaching Assistant for course 15.871 Introduction to System Dynamics
Period: 7 Jan 2017 → 15 Apr 2017
Daniel Alberto Sepúlveda Estay (Participant)
Department of Management Engineering
Management Science
Transport DTU

Description
15.871 and 872 introduce you to system dynamics modeling for the analysis of business policy and strategy. You will learn
to visualize a business organization in terms of the structures and policies that create dynamics and regulate performance. System dynamics allows us to create ‘microworlds,’ management flight simulators where space and time can be compressed, slowed, and stopped so we can experience the long-term side effects of decisions, systematically explore new strategies, and develop our understanding of complex systems. In these system dynamics courses we use simulation models, case studies, and management flight simulators to develop principles of policy design for successful management of complex strategies. Case studies of successful strategy design and implementation using system dynamics will be stressed. We consider the use of systems thinking to promote effective organizational learning. The principal purpose of modeling is to improve our understanding of the ways in which an organization’s performance is related to its internal structure and operating policies as well as those of customers, competitors, suppliers, and other stakeholders.

During the course students use several simulation models to explore such strategic issues as fluctuating sales, production and earnings; market growth and stagnation; the diffusion of new technologies; the use and reliability of forecasts; the
rationality of business decision making; and applications in health care, energy policy, environmental sustainability, and other topics.

Students learn to recognize and deal with situations where policy interventions are likely to be delayed, diluted, or defeated by unanticipated reactions and side effects. You will have a chance to use state of the art software for computer simulation and gaming. Assignments give hands-on experience in developing and testing computer simulation models in diverse settings.

Accelerating Energy Efficiency through Network Analysis
Period: 27 Sep 2016
Xiao Wang (Invited speaker)
"Accelerating Energy Efficiency through Network Analysis" by Xiao Wang introduced the audience to the Global Energy Efficiency Accelerator Platform's partnership identification and mapping tool. This tool was developed in collaboration with the Net-Sights team to map the accelerators' vast network of committed jurisdictions, companies, and partner organisations, helping to identify partners for collaborative energy efficiency projects and any gaps in the network that need strengthening.

The workshop aims to discover a completely new approach to explore collaboration partnerships in the context of real cleantech challenges. It is targeted at decision makers in the areas of R&D, Design, and Manufacturing with responsibilities that include innovation management, new product development, and alliance formation.

This paper describes the structure of the Transtools3 freight transport chain choice model for Europe and the data at the shipment level that were used in estimation, and presents the estimation results and resulting elasticities. It also discusses the structure of the overall freight model and how production-consumption matrices from a trade model are combined with the transport chain choice model in model application. In the estimation of the transport chain choice model on the available disaggregate data sources (the Swedish Commodity Flow Survey 2009 and the French ECHO survey) we tested several options for the specification of transport costs in the model and various nesting structures.

**Period:** 8 Sep 2016 → 9 Sep 2016

**Aristeidis Tsakiris (Organizer)**

Department of Management Engineering

UNEP DTU Partnership

**Description**

In September 2016, the 10-Year Framework of Programmes on Sustainable Consumption and Production Patterns (10YFP) jointly with the Copenhagen Centre on Energy Efficiency (C2E2) held a workshop in Copenhagen, Denmark. This workshop had as objective to integrate energy efficiency into the six different 10YFP programmes. Energy efficiency is one of the most available and cost effective options for climate change mitigation. It contributes up to 50% of greenhouse gas reduction in current scenarios while delivering multiple co-benefits. It is also recognized as a key option for the sectors and themes covered by the 10YFP to contribute to the climate agenda.

Planning of Midwives
Period: 4 Jul 2016
Charlotte Vilhelmsen (Speaker)
Jesper Larsen (Other)

Department of Management Engineering
Management Science
Operations Research

Description
At a hospital in Denmark around 40 midwives support the pregnancy of approx. 6000 pregnant women every year. Their role is to monitor the pregnancies and prepare the women for labour. Based on the due date of a woman, authority guidelines prescribe specific and mostly rather narrow time windows within which the pregnant woman should have consultations with a midwife. Therefore, once a pregnant woman enters the system, here sequence of consultations for the time period until labour is fairly fixed. There is a clear goal that, as far as possible, each pregnant woman should see the same midwife at every consultation. Every week the newly arrived pregnant women are assigned an arbitrary free time slot belonging to a specific midwife. In turn this midwife is expected to have consultations with this woman in specific weeks according to the authority guidelines. This random assignment of pregnant woman to specific midwives, without any concern to the midwives’ future schedules, means that each midwife has a very unbalanced workload over the year. Furthermore, it means that there is an imbalance between the workloads of the different midwives. The aim of this project is therefore to devise a method that can make a fair distribution of pregnant women among the midwives. The distribution should result in a balanced work load for each midwife and a balanced work load among the midwives while at the same time making sure that the time windows for consultations are not violated.

GFEI Global Networking Meeting 2016
Period: 9 Jun 2016 → 10 Jun 2016
Aristeidis Tsakiris (Participant)
Department of Management Engineering
UNEP DTU Partnership

Description
The event brought together participants from all around the world. This includes G20 countries such as Canada, France, South Africa, Argentina, Brazil, Mexico and Indonesia, as well as developing countries such as Kenya, Uganda, Zimbabwe, Costa Rica, Panama, Malaysia and Vietnam.

The training included expert input and analysis on a range of topics, including an introduction to fuel economy concepts, in-depth training on fuel economy trends and developing country baselines to assess progress and inform cost-benefit analysis of different options. This year, the sessions also covered compliance and enforcement and expert panels on HDVs and electric vehicles. The event, which was held in collaboration with the Transport stream of the IEA’s Energy Efficiency training week is a unique global opportunity for practical learning, sharing experiences and expanding what works.

**IEA Energy Efficiency in Emerging Economies Training Week**
Aristeidis Tsakiris (Participant)
Department of Management Engineering
UNEP DTU Partnership

**Description**
The International Energy Agency (IEA) hosted its second Energy Efficiency in Emerging Economies Training Week from 6 - 10 June 2016 inclusive in Paris. This event is central to the IEA’s ongoing engagement with emerging economies.

This training event offers a combination of lectures, interactive discussions, practical exercises and a site visit. Advanced courses are offered on each of the following end-use sectors:

1) Buildings; 2) Lighting, Appliances and Equipment; 3) Industry; 4) Transport (co-hosted with the Global Fuel Economy Initiative (GFEI))

The courses will help participants ask the following questions regarding their countries’ energy efficiency policies: Where to start? What are the steps? Did it work? Where do I get help?

Also, cross-sectoral sessions on assessing the potential for energy efficiency, tracking progress, communication
campaigns and finance were offered to all participants. On day 3 of the training event, participants had the opportunity to take part in site visits, which were organised within Paris and were pertinent to the course participants choose to follow.

A special focus this year was on measuring the social and economic benefits of energy efficiency measures.

Energy Systems Analysis

**Description**
Abstract: The challenging task of adequately including sociological aspects as human behaviours related to transport in economy-energy-environment models, may enable an inclusive representation of the system under analysis, thus providing results which are closer to reality. This work represents a preliminary review of energy systems models where a sufficiently detailed representation of the transport sector is present. This in particular allows to study which transport-related behaviours are modelled in energy system models and which methods are adopted, with the aim of comprehensively understand the opportunities and challenges of such implementation in TIMES-DK. The analysis firstly provides a classification of economy-energy-environment models, according to the level of integration of the transport system, here emphasizing the need for clarifying the aggregation level required in the representation of the transport system in order to include human behaviours. The study subsequently reviews above 25 models where different transport-related behaviours were accounted for, highlighting on the one side the focus and direction of the current research and on the other side the overlooked aspects. The work thus offers a contribution in this research area, providing an updated overview of selected transport-related behaviours and the different possibilities for representing them in integrated energy and transport models.

Implementation and Performance Management

Description
International Journal of Workplace Health Management (IJWHM) publishes double blind peer-reviewed research and practitioner articles and case studies which identify risks and challenges, best practice and real-life implications for the individual, the employer and public health.

Coverage includes:
• Individual health – primary care and prevention, health education and promotion, attitudes, behaviour and lifestyle choice
• Workplace culture – organizational change, management policies/procedures, employer and employee education, the business case for workplace health promotion, communication and training, how culture affects mental health, violence, stress and work-life balance
• Physical issues – musculoskeletal health/ergonomics, occupational health and safety, legislation and compliance, disability management, workplace hazards, risk factor modification

IJWHM is a key resource for public and private organizations, government, researchers, human resources/senior management, unions and those who manage and promote workplace health.

Gaze interaction with textual user interface
Period: 21 Aug 2015
John Paulin Hansen (Lecturer)
Copenhagen Center for Health Technology
Department of Management Engineering
Technology and Innovation Management

Description
This presentation suggests using rapid serial visual presentation (RSVP) of single Words for prompting command options that may be executed by gaze-strokes. In a study with 27 participants the RSVP commands would engage a near-by display; adjust the speed of Word presentation; and provide a "back" option for text navigation. People readily understood how to execute RSVP command prompts and a majority of them preferred gaze input to a pen pointer. We present the concept of a smartwatch that can track eye movements and mediate command options whenever in proximity of intelligent devices that it connects with, i.e. a Gaze-Watch. For instance, standing next to a monitor, it may suggest to turn it on, if you look up at the monitor now. Command suggestions are provided in the RSVP-format, but they only stay active for a limited time, in which the gaze should be moved to apply them.

**The keys to success: Engineering your Business Model for international markets**
Period: 22 Jun 2015
Francesco Rosati (Speaker)
Department of Management Engineering
Technology and Innovation Management
Description
Customer segments, value propositions and business models
In this workshop, we introduced how our DTU task force can help you to develop, innovate and engineer your business model, helping you to make a fundamental difference in your business in international markets. We also demonstrated how we work with Danish SMEs in this regard by having the CEO and CSO of BluSense Diagnostics, one of our case companies, to demonstrate their experience of working with us to develop their business model.

Lean Product and Process Development
Period: 7 Apr 2015
Kasper Edwards (Organizer)
Department of Management Engineering
Production and Service Management
Implementation and Performance Management

Description
Today’s innovation economy is characterized by rapid changing markets disrupting old business models, with new markets arising quickly and unexpected driven by new technology and innovations. This stresses the time-to-market and hereby the product development process. Lean Product and Process Development (LPPD) is based on Toyotas Product Development System, Set Based Concurrent Engineering and the Agile/Scrum methodology from software developers. It gives you the means and method to manage a development project - quickly, while maintaining quality and safety and taking into account cost-investment. About Boaz Tamir Dr. Boaz Tamir has extensive experience in Lean Product & Process Development (LPPD) method as several startups founder, manager and entrepreneur. In his entrepreneurial, managerial-executive roles, sensei and consultancies activities Tamir led several Lean Transformation (turn around) processes. Collaborating with Jim Morgan, (Jointly with Jeffry Liker, the author of "The Toyota Product Development System") Tamir is currently deploying the LPPD approach combing the Lean Transformation Model (LTM) method and contributing his knowledge to some of the most successful High Tech organizations in Israel ("Startup Nation"). With extensive experience in entrepreneurship, company management and academic activity, Tamir has contributed his knowledge to the development of the business and marketing of some of Israel's most successful organizations. In his talk Tamir will examine the principles of LPPD that must guide the leader – who inspire change – as she endeavors to redesign an up-to-date Lean Management worldview.

**General Introduction to Foresight**  
Period: 16 Mar 2015  
Per Dannemand Andersen (Lecturer)  
Department of Management Engineering  
Technology and Innovation Management

**Description**  
The aim of the lecture is to provide the participants with a basic introduction to foresight and how foresight, in our opinion, relates to other policy formulation activities and in other future-oriented policy formulation activities (e.g. technology forecasting and futures studies). Furthermore, the lecture gives a brief introduction to quantitative and qualitative foresight methods – with emphasis set on the latter – and a brief introduction to overall design of foresight processes. The lecture will focus on foresight’s role in public science, technology and innovation policy.

---

**Horizon Scanning**  
Period: 16 Mar 2015  
Per Dannemand Andersen (Lecturer)  
Department of Management Engineering  
Technology and Innovation Management

**Description**  
The aim of the lecture is to provide the participants with a basic understanding of horizon scanning as a concept as well as the main approaches and sources. Furthermore, it is the aim to provide the participants with the basic knowledge to do a scan by searching early sign or weak signals. During the exercise, the participants determine proper data sources, research questions and search strings to scan the environment of an organisation. In this context horizon scanning is understood as a technique for detecting early warning signs or weak signals of potential significant changes in the environments and assumptions underlying the operation of the organisation.

**International Food and Agribusiness Management Review (Journal)**
Period: 2014 → …
Arne Wangel (Reviewer)
Department of Management Engineering
UNEP DTU Partnership

**Description**
The International Food and Agribusiness Management Review (IFAMR) publishes high quality, peer reviewed, scholarly articles on topics related to the practice of management in the food and agribusiness industry. The Journal provides managers, researchers and teachers a forum where they can publish and acquire research results, new ideas, applications of new knowledge, and discussions of issues important to the worldwide food and agribusiness system. The Review is published electronically on this website. The core values of the Review are as follows: excellent academic contributions; fast, thorough, and detailed peer reviews; building human capital through the development of good writing skills in scholars and students; broad international representation among authors, editors, and reviewers; a showcase for IFAMA’s unique industry-scholar relationship, and a facilitator of international debate, networking, and research in agribusiness. The Review welcomes scholarly articles on business, public policy, law and education pertaining to the global food system. Articles may be applied or theoretical, but must relevant to managers or management scholars studies, industry interviews, and book reviews are also welcome. The Review also reflects agribusiness scholarship worldwide with over half of its Editorial Board, Managing Editors, and article submissions coming from outside the United States.

Key variables of organisation design in servitization

Period: 2014
Melanie Kreye (Lecturer)
Department of Management Engineering
Production and Service Management
Engineering Systems Group

Description
Manufacturing companies offering additional service with their products need to change their organisation design to accommodate for the service business. Using the star model, this paper investigates organisation design in terms of strategy, structure, processes, rewards and people as a response to external environment to ensure performance. We present a case in the European renewable energy sector. The findings show three key variables: (i) processes need to enable information flow between business departments; (ii) servitization strategy needs to be translated into service-centred activities, and (iii) the parts of organisation design need to be aligned to prevent inconsistencies in service provision.

**Online Tutorial : Loop Eigenvalue Elasticity Analysis of System Dynamics Models**
Period: 2014 → …
Daniel Alberto Sepúlveda Estay (Participant)
Department of Management Engineering
Management Science
Transport DTU
Operations Management

**Description**
System Dynamics models are composed of different flow and state variables, with multiple interactions. In the process of identifying the relevant structure that leads to the observed behavior, the method of "Loop Eigenvalue Elasticity Analysis" (LEEA) can be very useful in quickly identifying the modes loops most relevant over time for this behavior.

The method was originally proposed by Kampmann and Oliva in 2006. This video is a tutorial that shows the implementation of such method when applied to a specific example.

The video first discusses the theory behind the analysis, then describes step by step the process of data gathering and processing, to finally describe the analysis of results.

In order to reproduce what is shown in the video, both VENSIM and Mathematica software packages are required.

Description
Bioenergy: electrification, decarbonization & development potential in Cameroon

The sixth Africa Carbon Forum (ACF) took place from 2-4 July 2014, in Windhoek, Namibia. The Forum will: inform attendees of developments in carbon markets; provide a venue for connecting carbon project developers and investors; showcase lessons from completed Clean Development Mechanism (CDM) projects in Africa; feature presentations on public and private sector strategies for promoting CDM benefits in Africa; and encourage networking and discussions among technical experts, project developers and carbon buyers. The Forum is organized by the UNFCCC Secretariat, the UN Environment Programme (UNEP), the UNEP DTU Partnership, the International Emissions Trading Association (IETA), the World Bank, and the African Development Bank (AfDB).

Description
We are on the verge of a paradigm shift in the way new knowledge is shared. The internet allows for complete openness for research, innovation and personal and government information. Openness to resources from academia, government and industry changes the playing field for citizens, scientists, inventors and industry allowing all to participate in innovation and value creation, regardless of geography and background. This session explores the balance between benefits and concerns in relation to openness to knowledge and data. It showcases the current impact potential of Open Science and Open Innovation, while considering intellectual property, the right for commercial exploitation of innovative concepts, and not least, the need for privacy legislation preventing misuse of personal data. The session is an experiment to eliminate the boundaries between research, innovation and social science, and explore the effects of an Open Attitude, based on the understanding that there is an inevitable paradigm shift across them all. The interactive session provides exposure to a multidisciplinary audience, that is appealing not only across scientific disciplines but also for citizens, industry and policy makers. Some of the questions to instigate the discussion include "Why should I care about openness?", "Does Open Science create more impact?", "Does intellectual property enable or hinder progress?", "Does openness pose risks for privacy and patients?".

Description
Objectives:
• Ensure that all participants understand the scientific context and UNFCCC origins of intended nationally determined contributions (hereafter referred to as contributions)
• Share experiences and best practices in developing contributions, and identify solutions to challenges being faced
• Address issues related to the underlying technical basis required to prepare robust, realistic and achievable contributions
• Identify support needs required to reach domestic agreement on contributions and follow-up actions in this regard

Participants:
Country representatives from the African Region, developed countries, multilateral and bilateral agencies, regional organisations, and resource experts.

Emmanuel Ackom (Invited speaker)
Department of Management Engineering
UNEP Risø Centre
Description
Discussions of economic development will always have industrialization, modernization and urbanization in the equation. But as this generation is a product of past environmental transgressions, we are now all inclined to include environmental sustainability in the picture. We no longer refer economic development to quantitative and qualitative progress in the economy, community and society, but we now also have to consider the kind of natural environment we would be leaving for future generations. Industrialization, modernization and urbanization translate to an insatiable thirst for energy but as demand for energy grows, so do the greenhouse gas emissions. If the aspiration of development is to raise living standards, provide proper access to modern energy services, more efficient use of energy to protect the global environment and ensure reliable energy supplies, then Green Sustainable Development must play a key role.

Incorporating elements of low-carbon green growth in economic strategies that would cover technological, financial and investment aspects, as well as national and regional energy development policies geared towards achieving a sustainable green future has now become more important. A low-carbon based type of economy will help mitigate environmental pollution and CO2 emissions caused by fossil fuel use, help reduce reliance to dwindling fossil reserves, and encourage technological innovations.

The 2014 International Conference and Utility Exhibition on: Green Energy for Sustainable Development on 19-21 March 2014 in Pattaya City, Thailand was to exchange research ideas, experiences, technical, social, financial, economic and policy issues covering greening energy utilization. Here, energy professionals, policy makers, researchers, members of the academe, engineers, members of the energy supply sector, etc., had a platform to showcase research findings, technological innovations, transformative emerging technologies, and even to discuss burning global, regional and national issues in energy utilization for development and environment policies and programmes.

**Description**
Hvordan bruger forskere og undervisere sociale medier i deres akademiske arbejde?
Er de sociale medier forskernes og undervisernes nye personlige bibliotekar?
Hvordan kan bibliotekerne udvikle sig for også fremover at spille en væsentlig rolle i formidling af viden?
Kan/skal vi nyfortolke informationskompetence-begrebet, hvis sociale medier bliver et centralt redskab for vores studerende, forskere og undervisere til at finde viden?

Det er nogle af de spørgsmål, vi vil diskutere på en temadag om sociale medier og deres rolle i akademisk praksis.

Oplægsholder og efterfølgende paneldeltager.

UNEP Risø Centre

**Description**
Energy, water and climate nexus: A case study of Cameroon

The Water Institute of the University of North Carolina at Chapel Hill and collaborators hosted the conference on March 5-8, 2014 to examine the thinking and actions related to a nexus approach. The conference brought together scientists and practitioners working in government, civil society, and business and other stakeholders focusing on the questions of how and why the nexus approach is, and can be, used on international and local levels.

**Main Conference Themes**
Building on the Water, Food and Energy Nexus Conference held in Bonn Germany in 2011, this conference aims to address four connected, but distinct relationships, with water being the central node of each nexus:
- Water-Climate
- Water-Energy
- Water-Food
- Energy-Food

Transport Modelling

Description
The focus of this study is departure time choice modeling of car commuters in the morning rush hours. To model this we use the approach first formulated by Small (1982), i.e. the Scheduling Model. This study will contribute to the research of departure time choice modeling in three distinct ways. Firstly, by designing an efficient stated choice design specifically built to capture the trade-offs being made in the choice of departure times. Secondly, to account for detailed level of flexibility not only in relation to the specific trip under question, but for trips and activities throughout a 24 hour time period. This is important because a crucial problem when studying departure time is that the choice of when to realize a given trip is (often) related to the full daily activity pattern, such as a restriction or a preference in one activity may form restrictions in the flexibility of other activities and thereby affects the preference for the related departure time. And thirdly, to incorporate latent variables to measure underlying preferences that potentially affect departure time following the Theory of Planned Behavior, as these preferences are believed to be an important factor in explaining behavior.

NAMAs for sustainable development: Assessing potential for transformational change in the Tanzania solar energy sector
Period: 6 Jan 2014 → 1 Jun 2014
Karen Holm Olsen (Guest lecturer)
UNEP Risø Centre
Department of Management Engineering

Description
The overall objective of this research is to understand how supported NAMAs could contribute to sustainable development and transformational changes in the sociotechnical systems in Tanzania. Specifically, the study intends to assess the practicability of NAMAs towards domestic policies which aim to alleviate poverty and achieve sustainable development through deployment of solar energy technologies. Given the special circumstances of the country, which is categorized by the UN as an LDC (UNCTAD, 2013), the focus will be on supported NAMAs as they likely to be the potential choice of NAMAs for Tanzania taking into account the poor economic situation.

Sustainable Development and Nationally Appropriate Mitigation Actions (NAMA): Examining Monitoring and Evaluation (M&E) approaches which might be suitable to assess the SD impact of NAMA projects.: Master thesis by Bodil Jacobsen
Period: 2 Jan 2014 → 15 Sep 2014
Karen Holm Olsen (Supervisor)
UNEP Risø Centre
Department of Management Engineering

Description
1. Assess the level of national ownership and country-driven approach into the MRV process. As the NAMA in general emerge from a country-driven and bottom up approach (motivating national ownerships and ‘appropriate actions’) it would be interesting to assess the level of ownership into the NAMA more broadly but specifically around the MRV process. There is a CDM Sustainable Development Tool, developed on behalf of the UNFCCC secretariat in 2012, which is voluntary for countries to use in regard to monitoring and reporting on NAMAs, however it is up to each individual country to come up with ‘domestic’ MRV systems leaning upon international guidelines. To date, however, there not been any mainstream methods developed for the MRV to assess SD impact of NAMAs. This dissertation could look at international guidelines on M&E e.g. from the development sector and assess how these might support measurement of SD evolving from NAMA projects, which again can feed into the MRV process.

Supervisor for intern at URC - master student.

The Industrial PhD Programme Committee (External organisation)
Period: 1 Jan 2014 → 31 Dec 2017
Christian Thuesen (Participant)
Department of Management Engineering
Production and Service Management
Engineering Systems Group

Description
The Industrial PhD Programme Committee (IPPC) is appointed by The Danish Council for Technology and Innovation (DCTI). The committee has 25 members and can be supplemented with members appointed by the Minister.

IPPC is an ad hoc committee, and DCTI has the decision making authority. The task for IPPC is to evaluate applications for the Industrial PhD Programme, and IPPC recommends the marking (approved/conditionally approved/rejected) to DCTI. The authorization to approve/reject applications is lawfully delegated by DCTI to The Danish Agency for Science, Technology and Innovation, and the latter makes the final decision on approving/rejecting applications.

Review of the Green Growth Best Practice Assessment Report 2013 (External organisation)
Period: 21 Aug 2013 → 8 Jan 2014
Karen Holm Olsen (Member)
UNEP Risø Centre
Department of Management Engineering

**Description**
The Green Growth Best Practice (GGBP) initiative is an effort to assess green growth planning and implementation practices around the world and find what works best under what circumstances, to assist policy makers and practitioners to improve the quality of green growth efforts.

The Green Growth Best Practice (GGBP) initiative seeks to improve the quality of green growth planning and implementation through amalgamating, analysing and actively drawing and sharing best practices from global experience to date.

Your role as reviewer serves three key purposes: Improve the quality of the research: your rigorous review helps us to sharpen the focus of the chapter, hone key points and correct inaccuracies Identify gaps: your knowledge and expertise helps us identify other experiences and sources of information that will address key gaps in the analysis. Refine the communication of results: especially to clearly present practical lessons and information that can strengthen ongoing green growth plans and programs around the world. In your comments please keep in mind that you will have the opportunity to see and provide further feedback on the changes made by authors in response to your comments during the review of the Second Order Draft which will start on November 16th 2013. Please be frank and ambitious in your comments!

**Degree of recognition:** International

European Cooperation in Science and Technology 'action' to strengthen a European network of researchers in structured expert judgement (External organisation)
Period: 1 Jul 2013 → 30 Jun 2016
Daniel Puig (Participant)
Department of Management Engineering
UNEP Rise Centre

Description
ISCH COST Action IS1304.

I act as the representative of Denmark in the Management Committee of the European Union's ISCH COST Action IS1304, which seeks to improve the use of structured expert judgement for decision making. I contribute to the work of two of the five working groups - one looking at how structured expert judgement compares to other techniques, notably Bayesian probabilistic projections, and a second one focused on documenting examples of practical application of structured expert judgement.

Body type: Inter-governmental
Degree of recognition: International

European FM researcher of the year
Rikke Brinkø Berg (Recipient)
Description
FM Researcher of the year is an award, which recognises the value of research being undertaken across Europe. The research must address the EuroFM research agenda and contribute to its overall objectives to advance knowledge in FM and promote its effective application in practice and education. Read more about the competition below.

Details
Awarded date: 8 Jun 2016
Prize: Prizes, scholarships, distinctions

European FM Researcher of the Year
Giulia Nardelli (Recipient)
Department of Management Engineering, Production and Service Management, Centre for Facilities Management, Implementation and Performance Management

Description
Awarded during European Facilities Management Conference (EFMC) 2014 in Berlin (DE).

Details
Awarded date: Jun 2014
Degree of recognition: International
Granting Organisations: EuroFM
Prize: Prizes, scholarships, distinctions

Hedorfs Fonds Pris for Transportforskning, 2011

Awarded date: 2009
Granting Organisations: Danish Agency for Science Technology and Innovation
Prize: Prizes, scholarships, distinctions

**INFORMS Railway Application Section 2016 Student Paper Award - Second Place**
Fabrizio Cerreto (Recipient), Otto Anker Nielsen (Recipient) & Steven Harrod (Recipient)
Department of Management Engineering, Transport DTU, Transport Modelling, Management Science

**Description**
RAS (Railway Applications Section), a subdivision of INFORMS (Institute for Operations Research and Management Sciences), is sponsoring a student research paper contest on analytics and fact-based decision making in railway applications.

Operations Research (OR) and the Management Sciences (MS) are professional disciplines that deal with the application of information technology for informed decision making. OR/MS professionals aim to provide rational bases for decision making by seeking to understand and structure complex situations and to use this understanding to predict system behavior and improve system performance. Much of this work is done using analytical and numerical techniques to develop and manipulate mathematical and computer models of organizational systems composed of people, machines, and procedures. RAS provides a forum for bringing together practitioners, consultants, and academics interested in applying OR/MS techniques to the railroad industry. RAS activities include roundtables, paper sessions at INFORMS national meetings, workshops, and focus groups. Roundtables provide attendees with a unique opportunity to explore, in-depth, topics ranging from eBusiness to simulation to network modeling together with a panel of experts. Paper sessions feature the latest in OR/MS research pertaining to the rail industry.

**Details**
Awarded date: 13 Nov 2016
Degree of recognition: International
Granting Organisations: INFORMS
Event: INFORMS Nashville 2016 Annual Meeting

Awarded date: 1 Apr 2013
Granting Organisations: Idella
Prize: Prizes, scholarships, distinctions

The TIM Division Award for Best Reviewer 2017 (AOM)
Sabrina Woltmann (Recipient)
Department of Applied Mathematics and Computer Science, Department of Management Engineering, Technology and Innovation Management

Description
TIM reviewers that distinguished themselves for the timeliness and constructiveness of their comments. It is based both on authors’ evaluation and the TIM officers’ own reading of your reports.

Details
Awarded date: 8 Aug 2017
event: Academy of Management 2017
Prize: Prizes, scholarships, distinctions

TRAVISIONS COMPETITION 2016: Second place in Rail
Fabrizio Cerreto (Recipient)
Traffic modelling and planning, Department of Management Engineering

Description
The student competition aimed at university and technical institute students pursuing bachelor degrees and higher. Initially, participants were invited to submit an abstract under one of the TRA2016 conference topics: Environment – Decarbonisation, Sustainability and Energy Efficiency Vehicles & Vessels Technologies, Design and Production Urban and Long-Distance People Mobility - Systems and Services Freight Transport and Logistics Safe, Secure and Resilient Transport Systems Transport Infrastructures Human Factors, Socio-Economics and Foresights Automation and Connectivity Enabling Environment for Innovation Implementation All participants were invited to register their ideas and...
submit a Title and a short abstract by January 2016. They also had until the end of January to develop and submit their idea, which was meant to be a report based on the Final Project Template accompanied by any supporting documents. This was followed by an Evaluation of Ideas period during which a judging panel determined which were the top three ideas per mode. Some 130 students participated, submitting a total of 107 student projects from 14 different EU countries and 35 different universities. Here are the three winners of each category.

Cyber attacks on supply chains are a constant threat to organizations. News media are regularly reporting cyber attacks to supply chains that result in data theft or denial of service. Examples abound, such as the theft of credit card data for 70 million customers from Target in 2013, and a sophisticated distributed attack that blocked the websites of major companies in the east-US such as Amazon, Starbucks and PayPal, during most the 21st of October 2016. Although relevant, this coverage often overshadows cyber-attacks that affect supply chain operations, which continue to occur without media attention. This is giving hackers free range to refine and practice their techniques for increased penetration and damage, resulting in a whole different range of disruptions such as container theft, intervention of plant operation, or misallocation of payments, for example.

The MIT Center for Transportation & Logistics (CTL) will host a webinar to address hacker-related vulnerabilities in supply chain operations. At the root of this problem lies the structure of data exchanges between supply chain partners. Key questions for supply chain managers include:

- How does your supply chain manage these data exchanges?
- How much are you assigning these problems to IT even though they have direct impact on operations?
- How does your supply chain prevent these attacks, or react when these attacks happen?

Dr. Jim Rice and Daniel Sepulveda, PhD student, will address these questions, and talk about research findings that offer a deeper understanding of the structures that supply chains can use to improve their response from hacker attacks so as to minimize operational disruption and allow a more efficient recovery.

Dr. Jim Rice and Daniel Sepulveda, PhD student, will address these questions, and talk about research findings that offer a deeper understanding of the structures that supply chains can use to improve their response from hacker attacks so as to minimize operational disruption and allow a more efficient recovery.

Ekspert: Interessant med nye tal
Altinget har også fremlagt vismændenes kritik til de tre eksperter i afgifts- og tilskudsanalysens referencegruppe. Her har kun en, Henrik Klinge Jacobsen, professor MSO ved DTU, haft mulighed for at svare.
Han vurderer ikke, at kritikken af Skatteministeriet ændrer "markant" på den kvalitative konklusion: Der er en samfundsmæssig gevinst ved at reducere partikelemissioner fra brændeovne i tæt befolkede områder, selv når der tages hensyn til omkostninger ved reguleringen.
"Men det er selvfølgelig interessant at se, hvor meget et andet og nyere bud på skadesomkostninger påvirker samfundsekonominiske gevinter ved regulering i forhold til omkostninger ved reguleringer," skriver Henrik Klinge Jacobsen i et svar til Altinget.

Webinar: Visuals Matter: Using Effective Visuals to Support Project and Portfolio Decisions
Joana Geraldi
10/12/2016

Description
Dr Joana Geraldi (associate professor at the Engineering Systems Division) and Dr Mario Arlt (newly appointed adjunct professor) conducted a life webinar broadcasted by PMI and Projectmanagement.com on the impact of visuals on cognition and communication in projects, programs and portfolio decisions and communication practices. The goal of the webinar was to increase project practitioners' and scholars' awareness about the importance of visuals and to provide guidance on how to use visuals strategically. The webinar is based on a book published in 2015 about the topic. It is available for viewing at the projectmanagement.com, and has been viewed by over 3,000 people (as of January 2017). PhD, Sara Shafiee, DTU Management Engineering and Haldor Topsøe: PhD, Sara Shafiee, DTU Management Engineering and Haldor Topsøe
Sara Shafiee
28/10/2016

This film is produced for DTU’s celebration of the new PhD graduates 2016, and is about Sara Shafiee, how is doing an industrial PhD about: “Conceptual Modelling for Product Configuration Systems” in collaboration between DTU Management Engineering and Haldor Topsøe.

Farligt, mindre hensynsfuldt og fyldt med egoister: Danskernes dom over trafikken er hård: Trafikken er blevet farligere de senere år, mener danskerne ifølge en undersøgelse, Kantar Gallup har lavet for Gjensidige Forsikring. Men billedet stemmer ikke overens med statistikkerne, påpeger forskere.

Facility Management - Service Elevators: Big outsourcing firms find that escaping the crowd is not so easy
Per Anker Jensen
15/03/2014

Description
The article concerns the challenges for large multinational service providers on the Facility Management market.

The article finishes with the following quote: Per Anker Jensen of the Technical University of Denmark says that, as in other crowded industries, the survivors in the outsourcing game will have to do better than just offer the keenest prices: they will need to be innovators, constantly coming up with useful new services that their clients never realised they needed.

Description
The way in which securities are traded is very different from the idealized picture of a frictionless and self-equilibrating market offered by the typical finance textbook. Market Liquidity aims to confront many puzzling phenomena in securities markets and uses the analytical tools and empirical methods of market microstructure to understand them. These include issues such as why liquidity changes over time, why large trades move prices up or down, and why these price changes are subsequently reversed, and why some traders willingly disclose their intended trades while others hide them.

Book Review: Inventing the Market: Smith, Hegel & Political Theory by Liza Herzog
Luis Rafael Boscán Flores
22/08/2013

Description
Inventing the Market: Smith, Hegel, and Political Theory analyses the constructions of the market in the thought of Adam Smith and Georg Wilhelm Friedrich Hegel and discusses their relevance for contemporary political philosophy. Combining the history of ideas with systematic analysis, it contrasts Smith’s view of the market as a benevolently designed ‘contrivance of nature’ with Hegel’s view of the market as a ‘relic of the state of nature.’ As the various prizes won by Herzog for this work confirm, this is an excellent scholarly effort, concludes Luis Boscán.

Book Review: America’s Blind Spot: Chávez, Oil and US Security by Andrés Cala and Michael Economides
Luis Rafael Boscán Flores
22/05/2013

Description
Latin America holds some of the world’s biggest oil reserves, but unstable political events in the region are hindering its potential, especially in Venezuela. Global U.S. security would benefit from a revamping of outdated policies towards Latin America, argue Andrés Cala and Michael Economides. This is a blind spot in American politics, one that threatens U.S. geopolitical and economic interests. In this book, the authors aim to offer a thorough analysis of key geopolitical and economic threats to the U.S., highlighting the need for a new Latin American policy doctrine based on military and strategic priorities. Reviewed by Luis Boscán.

Defining employees
Zaza Nadja Lee Herbert-Hansen
06/06/2012

Description
Doctoral candidates should be considered employees, not students, argues the European Council of Doctoral Candidates and Junior Researchers (Eurodoc) in Brussels. According to the council's 17 May statement, PhD candidates' access to benefits and training is jeopardized if they are not designated as employees. In some cases, PhD trainees cannot access their institution's intranet and research databases, notes Zaza Nadja Lee Hansen, Eurodoc's career development workgroup coordinator. Universities in some European countries consider PhD candidates neither students nor employees, Hansen says, but adds that other nations, including Germany and Austria, recognize them as university employees.
