Occupant response to different correlated colour temperatures of white LED lighting

Correlated Colour Temperature (CCT) of lighting may affect not only occupant visual perception, but also other indoor environment perceptions, such as perceptions of the thermal environment or the air quality. This study aimed at quantifying the association between CCT of white LED lighting and subjective perceptions and performance at operative temperatures at the upper and lower borders and in the middle of the comfort range. Higher CCT was significantly associated with decreasing thermal sensation, but only at the thermally neutral condition. Female subjects responded stronger to changes in CCT than male subjects. Under all temperature conditions, CCT was clearly associated with the perceived brightness of the light, and at 22 °C also with the perceived air quality and with subjectively assessed alertness. CCT had no effect on the measured performance of a d2 task. At 22 °C, the observed decrease in thermal sensation when CCT went from 2700 K to 6200 K was equivalent to a difference in operative temperature of 1.7 °C. With an assumed neutral CCT of 4500 K (middle of range), a decreased heating set point in an office building, corresponding to an equivalent shift in CCT from 4500 K to 2700 K, resulted in a reduction of around 8% of the building's total annual energy use. However, this assumes ideal conditions without influence from daylight, light from PC monitors, or coloured surfaces and other potentially disturbing factors.

Development of white LED illuminants for colorimetry and recommendation of white LED reference spectrum for photometry

General lighting is undergoing a revolutionary change towards LED-based technologies. To provide firm scientific basis for the related colorimetric and photometric measurements, this paper presents the development of new white-LED-based illuminants for colorimetry, and their evaluation to recommend a new reference spectrum for calibration of photometers. Spectra of 1516 LED products were measured and used to calculate eight representative spectral power distributions for LED sources of different correlated colour temperature categories. The suitability of the calculated representative spectra for photometer calibration was studied by comparing average spectral mismatch errors with CIE Standard Illuminant A, which has been used for decades as the reference spectrum for incandescent standard lamps in calibration of photometers. It was found that in general, when compared with Standard Illuminant A, all the potential LED calibration spectra reduced spectral mismatch errors when measuring LED products. Out of the potential LED calibration spectra tested, the white LED spectrum with correlated colour temperature of 4103 K was found to be the most suitable candidate to complement Standard Illuminant A in luminous responsivity calibrations of photometers. When compared with Standard Illuminant A, employing the 4103 K reference spectrum reduced the spectral mismatch errors, on average, by approximately a factor of two in measurements of LED products and lighting. Furthermore, the new LED reference spectrum was found to reduce the spectral mismatch errors in measurements of daylight, and many types of fluorescent and discharge lamps, indicating that the proposed reference spectrum is a viable alternative to Standard Illuminant A for calibration of photometers.

Direct Beam and Diffuse Spectral Irradiance Measurements in a Nordic Country Analyzed With the Average Photon Energy Parameter
One year of spectrally resolved direct normal irradiance (DNI), diffuse horizontal irradiance (DfHI) and global horizontal irradiance (GHI) measured in Roskilde, Denmark are analyzed in terms of the average photon energy (APE). We show that the APE of the GHI component is characterized by spectral distributions with low standard deviations, which is consistent with the findings of previous authors. In contrast, the APE of the DfHI and DNI components show spectral distributions with higher standard deviations, which suggests that a given APE value for DNI or DfHI can represent a wider array of spectral distributions. Finally, it is shown that the DfHI APE is characterized by high energy spectral distributions, which has particular significance in the case of building integrated photovoltaic (BIPV) applications in Nordic countries.

**LEDMET Report: Simulation and correction of stray light in spectrometers**

In this report, stray light is described as a source of uncertainty in spectrometers and spectroradiometers, and through simulation of various kinds of stray light we show the effects these have on the derived quantities of the spectral measurements. The simulated stray light is then sought corrected by the method developed by Zong et al. at NIST and the derived quantities are then compared to the original data. This report is the deliverable of milestone M1.3 in project Center
for LED Metrology (LEDMET).

Occupant response to controllable LED lighting
At three different ambient temperatures, human subjects were exposed to correlated colour temperatures (CCT) in the range 2750 to 6230 K at an illuminance of 1000 lux. Significant associations were found between CCT and thermal sensation and between CCT and perceived stuffiness of the air.

Outdoor Electroluminescence Acquisition Using a Movable Testbed
The experimentation with a movable outdoor electroluminescence (EL) testbed is performed in this work. For EL inspections of PV power plants, the fastest scenario will include the use of unmanned aerial vehicle (UAV) performing image acquisition in continuous motion. With this motivation, we investigate the EL image quality of an acquisition in motion and the extent of image processing required to correct scene displacement. The results show processed EL images with a high level of information even when acquired at 1 m/s camera speed and at frame rate of 120 fps.

Spectrometric Instrumentation For In-Situ Monitoring Of Spectral Components
We present a spectrometric instrumentation to monitor and log the spectral characteristics of the light in hospital rooms over long term periods during a trial of the effect of controlled lighting on patients. Each room has been equipped with a dynamic lighting system enabling change of correlated colour temperature of the light over the day. The objective is to estimate and document the available light exposure to the patient including the daylight through the window. The calibrated spectral measurements allows for evaluating the stimulus intensities for all five photopigments in relation to both visual and non-visual effects of the light in the rooms.

Spectrometric Instrumentation for in Situ Monitoring of Spectral Components in Dynamic Lighting Scenarios

We present a spectrometric instrumentation to monitor and log the spectral characteristics of the light in hospital rooms over long term periods during a trial of the effect of controlled lighting on patients. Each room has been equipped with a dynamic lighting system enabling change of correlated colour temperature of the light over the day. The objective is to estimate and document the available light exposure to the patient including the daylight through the window. The calibrated spectral measurements allows for evaluating the stimulus intensities for all five photopigments in relation to both visual and non-visual effects of the light in the rooms.

1. Motivation, specific objective:
There is a growing focus on daylight and artificial light in the fields of health and psychiatry as an element that can support conventional medical treatment. In this project daylight is combined with a LED based dynamic luminaires so there is a need for documentation of the light conditions during the interventions. The objective is to provide calibrated spectral irradiance measurements in the rooms to monitor and log the spectral characteristics of the light in the long term trials and to be able to quantify the difference in lighting conditions in a dynamically controlled and not controlled room. The calibrated spectral measurements allows for evaluating the stimulus for all five photopigments as recommended by CIE using the α-opic irradiances, i.e. cyanopic, chloropic, erythropic, melanopic and rhodopic irradiances measured in W/m². The applied spectral sensors needs to be small and unobtrusive not to be disturbing in the hospital room, they further need to be sensitive to low light conditions and they need to be inexpensive. Normal spectrometers do not comply with these requirements and for this setup new types of spectral sensors have been investigated and chosen for the measurement system.

2. Methods:
A spectral sensor of the so-called “Pancake” configuration is used for the measurements. It consists of a linearly variable filter on top of an array detector chip and allows for spectral measurements from 380 to 700 nm. The spectral resolution is around 5-9 nm. With USB connection the sensor weighs 15 g and has a size of 10x22x38 mm³. It is a low cost sensor, less than one fifth of price of handheld spectrometers, allowing for inexpensive multipoint measurements. The spectral sensor itself has a narrow acceptance angle and for the ambient light measurements a cosine response is required.

Therefore, the sensors has been installed in small metal boxes with a hemispherical diffuser in front of the sensor array. Prior to the installation at the hospital these sensor boxes has been calibrated for spectral irradiance in the photometric laboratory using a 1000 W FEL standard spectral irradiance lamp at a distance of 50 cm. Further the sensors has been characterised for dark noise and spectra for the used integration times has been saved. Both dark correction and calibration is applied in the pc control program. The control program has been developed to subsequently take measurements from all the installed spectral sensors and store the measured and calibrated spectral power distributions with a timestamp and serial number for the sensor. Prior to each measurement the program automatically finds the optimal integration time for the current light conditions, ensuring no saturation and a good signal level of more than 60 % of the saturation level. The possible integration times has been restricted to 72 from 10 μs to 10 s. In each of four rooms, three sensors has been installed to monitor the light conditions. One sensor is placed at the top of the window on the end wall measuring the daylight entering the room. The other two sensors are placed on each side wall approximately 1.5 m from the end wall with the window and at a height of 1.5 m. The three sensors in a room are connected to a USB-Ethernet hub. The sensor boxes are painted white and no wires are visible, which is essential in the hospital ward. All twelve spectral sensors are connected to a pc via an Ethernet switch. The sensors are powered through the The spectral data logging system runs with no internet access to comply with patient data regulation.

3. Results:
The sensors has been installed and will be monitoring and logging spectral data in the four hospital rooms from April 2018 onwards. Data will be collected and presented to show the effect of the different lighting conditions in the rooms, e.g. on the α-opic irradiances. Test of the spectral sensors compared to calibrated spectroradiometers will also be done and presented.

4. Conclusions:
An instrumentation system to monitor and log the spectral characteristics of the light in hospital rooms over long term during a trial of controlled lighting on patients has been described. The spectral sensors applied full fills the requirements of being small and unobtrusive, and inexpensive allowing many measurement positions and continuous logging.

Warm or Cold Feelings: Estimating Biases in Field Studies

1. Motivation, specific objective: Lighting systems with LEDs that allows for control of illumination, in terms of the correlated colour temperature (CCT) and illuminance intensity, is currently being introduced widely in buildings resulting in decreased energy use for lighting systems. There is a great focus on reducing the overall energy use for buildings and the major energy-consuming factor in buildings is related to the regulation of thermal sensation. An earlier laboratory study with few biases showed that a shift in thermal sensation could occur when changing the lighting by altering the CCT. Using intelligent lighting control could therefore potentially benefit the overall energy use for buildings if being integrated in the thermal strategy. The overall objectives were to test if it is possible to detect an effect similar to the findings from the laboratory study on the thermal sensation when altering the CCT in real offices environments. The objective of this abstract is to discuss the experimental setup imposed in our field study where supplemental lighting is influenced by daylight and other strong biases. Differences that relate to biases should be estimated and accounted for, but the amount of controls are on the expenses of possible tests of the treatments in focus.

2. Methods: In a real office setting, we test the influence of three different CCT’s of 2800, 3100 and 4000 K on the workers thermal sensation and preferences. Three similar hallways and adjacent single or double offices at the Danish Technical University, Denmark (55°41'38.5"N 12°6'5.7"E) were used. These sections were equipped with LED lighting with central control of CCT and light levels. During the field study the light was on at all times starting from 7 am and onwards unless the workers purposely turned off the light. The electric lighting system was adjusted to 650lx at table height in all CCT settings and it was not possible to regulate the light intensity. The offices had windows to the outside, facing East or West.

The experiment was conducted primo January 2018 and lasted for seven weeks. The period was carefully selected to revisit the performance of participant laboratories and highlights the importance of inter-laboratory comparisons, showing the possible improvements in measurement reproducibility.
questionnaire with ten (10) specific questions sent out once a week. The workers were asked to rate their individual sensation of the lighting and thermal comfort while situated in their office. Indoor climate measured as the temperature, RH and CO2 concentration in the offices during the experiment were logged every 5 minutes along with measurements of outdoor diffuse and direct radiation, temperature and humidity in order to exclude them as possible bias.

3. Results and discussion: This field study differed from (most) laboratory studies in its duration and number of biases. In real office settings, we investigate longer term effects of differences in supplemental lighting CCT on the workers. The workers and sections differed in various ways. Thus, the anchor weeks with CCT of 3100 K in all sections was imposed, to estimate the differences between sections, biases of dealing with different groups of people (sections) along with the influences of continuous changes in the outdoor radiation. The questionnaire lead to a relatively consistent response rate – resulting in between 28-31 answers the first three weeks and between 20-24 answers the last four weeks (out of 48 requests). The response rate on our questionnaire was in average around 50%, which partly reflect its' length. A short questionnaire, opposed to a more extensive questionnaire, did not allow us to ask question, of e.g. work related distractions, tiredness, stress or sound levels, to further include and account for such biases in later findings, but we do not find that a lower response rate would have been advantageous. The differences being present between the sections were by anchor weeks measured once for each rotation and at the end. However, imposing the anchor weeks compromised the amount of answers in relations to the treatments of 2800 and 4000 K and extended the test period. Our weekly sent questionnaires (7 weeks) were answered by 19, 135 and 26 workers (180 in total), in relation to treatment settings of 2800, 3100 and 4000 K, respectively. If the study was conducted without the four anchor weeks the test period alone would have been 3 weeks. Execution within 3 weeks would have resulted in a higher response-rate and a more balanced number of answers in relation to the imposed treatments. However, this would compromise the measure of differences that relates to biases influencing the treatment effects. The need of controls for biases will depend on the treatment strength.

4. Conclusions: Field experiments are characterized by having many biases and often a weaker response rate on questionnaire surveys. Our online questionnaire of 10 questions sent out once per week in a field study resulted in an average response rate around 50%. The response rate declined slightly after 3 weeks and varied between 42% and 65%. We are unsure of the need for imposed anchor weeks, since the need for controls of biases influencing the overall result will depend on the treatment strength and survey response rates. However, we stress that differences that relate to biases should be estimated and accounted for.

Assessment of filament led bulbs with respect to temporal light artefacts
Temporal light artefacts, abbreviated TLAs (including flicker, stroboscopic effect and phantom arrays), i.e. undesired time modulation in luminance from a light source, has shown to be a threat to wider SSL adoption especially related to dimming functions and low-quality LED products. This is due to the effects that both noticeable and unperceivable TLAs have on human perception and wellbeing. In the present work a number of filament LED bulbs, currently available on the market, are assessed primarily with respect to TLAs, but also with respect to photometric, colorimetric and efficiency properties. The investigation shows that only one of the 10 investigated lamps can be considered flicker free. The rest of the lamps the TLAs are of such a magnitude that none of them fulfil the suggested recommendations currently available.

Solid-state lighting (SSL) products are already in use by consumers and are rapidly gaining the lighting market. Especially, white Light Emitting Diode (LED) sources are replacing banned incandescent lamps and other lighting technologies in most general lighting applications. The aim of this work is to develop LED-based illuminants that describe typical white LED products based on their Spectral Power Distributions (SPDs). Some of these new illuminants will be recommended in the update of the CIE publication 15 on colorimetry with the other typical illuminants, and among them, some could be used to complement the CIE standard illuminant A for calibration use in photometry.

**Development of outdoor luminescence imaging for drone-based PV array inspection**

This work has the goal to perform outdoor defect detection imaging that will be used in a fast, accurate and automatic drone-based survey system for PV power plants. The imaging development focuses on techniques that do not require electrical contact, permitting automatic drone inspections to be perform quicker and with less manpower. The final inspection method will combine several techniques such as, infrared (IR), electroluminescence (EL), photoluminescence (PL), and visual imaging. Solar plant inspection in the future can be restricted only by imaging speed requirements, allowing an entire new perspective in large-scale PV inspection.
This work has the goal to examine experimentally PV module imaging methods under natural light conditions, that will be used in a fast, accurate and automatic drone-based inspection system for PV power plants.
Indoor measurement of angle resolved light absorption by antireflective glass in solar panels

In this work, we present measurements of angle resolved light absorption of antireflective (AR) glass of PV samples, performed indoors using a collimated high radiance broadband light source. This indoor method proved to be viable and offered a significant simplification compared to outdoor measurements with trackers. The experimental results showed optical responses that are stable and suitable for indoor characterization of solar cells. We find the characteristic optical response of six different antireflective glasses, and based on such measurements, we perform PVsyst simulations and present the monthly DC energy production estimates across four distinct latitudinal locations with six different glass types. The results indicated that the AR glasses present different optical effects at the angles intervals between 0 – 45° and 60 – 90° and that the Diffuse AR glass can improve monthly yields by as much as 2% relatively to a bare cell.

Indoor Measurement of Angle Resolved Light Absorption by Black Silicon

Angle resolved optical spectroscopy of photovoltaic (PV) samples gives crucial information on PV panels under realistic working conditions. Here, we introduce measurements of angle resolved light absorption by PV cells, performed indoors using a collimated high radiance broadband light source. Our indoor method offers a significant simplification as compared to measurements by solar trackers. As a proof-of-concept demonstration, we show characterization of black silicon solar cells. The experimental results showed stable and reliable optical responses that makes our setup suitable for indoor, angle resolved characterization of solar cells.

Investigation of saturation effects in ceramic phosphors for laser lighting

We report observation of saturation effects in a Ce:LuAG and Eu-doped nitride ceramic phosphor for conversion of blue laser light for white light generation. The luminous flux from the phosphors material increases linearly with the input power until saturation effects limit the conversion. It is shown, that the temperature of the phosphor layer influences the saturation power level and the conversion efficiency. It is also shown that the correlated color temperature (CCT), phosphor conversion efficiency and color rendering index (CRI) are dependent both on incident power and spot size diameter of the illumination. A phosphor conversion efficiency up to 140.8 lm/W with CRI of 89.4 was achieved. The saturation in a ceramic phosphor, when illuminated by high intensity laser diodes, is estimated to play the main role in limiting the available lumiance from laser based lighting systems.
In this paper, we will present a setup with laser driven light source (LDLS) for measuring a 2D bidirectional reflectance distribution function (BRDF). We have carried out measurements to acquire the BRDF of different samples based on our setup: which consists of a new laser driven broadband light source (UV-VIS-NIR), spectroradiometer and sample holder stepper motor in a dark UV-protected environment. Here, we introduced a special kind of light source which has a bright, stable, broad spectral range and well collimated light output to give a very good angular resolution. The experimental results show how stable and reliable is our light source in terms of spectral power distribution, and in BRDF measurement. Furthermore we have shown that we are able to get a well collimated beam and higher power output using set of off-axis parabolic mirrors.

**Light source characterization and air movement under CIE S 025**

In 2015, the International Commission on Illumination (CIE) published the standard CIE S 025/E:2015 Test Method for LED Lamps, LED Luminaires and LED Modules. This document contains a number of standard test conditions, including laboratory room preparation, environmental and electrical provisions as well as requirements for the performance of testing and measurement equipment. One of the environmental considerations is a restriction of the airflow incident on the device under test. The sensitivity of LED source based devices to airflow is important for estimating the uncertainty originating from airflow. We find that for most of the tested devices the sensitivity is on the order of 5 %/(m/s), which is consistent with CIE S 025. However, we also found an example of a device with a larger sensitivity. Additionally we study general airflow measurements and influence of turbulence.
Luminescence Imaging Strategies for Drone-Based PV Array Inspection

The goal of this work is to develop outdoor defect detection imaging and understand fully its challenges and limitations. The imaging is based on luminescence strategies that will be used for fast and accurate UAV-based inspection system for PV power plants. We studied electroluminescence (EL) acquisition under natural light conditions during several times of the day, under high sun irradiation, to unveil the sunlight noise characteristics towards an InGaAs detector. In order to bring more freedom to a drone-based inspection, we also show the preliminary results of a laser-line based photoluminescence (PL) strategy as a viable method for an outdoor module PL imaging system.

Monte Carlo analysis of a control technique for a tunable white lighting system

A simulated colour control mechanism for a multi-coloured LED lighting system is presented. The system achieves adjustable and stable white light output and allows for system-to-system reproducibility after application of the control mechanism. The control unit works using a pre-calibrated lookup table for an experimentally realized system, with a
calibrated tristimulus colour sensor. A Monte Carlo simulation is used to examine the system performance concerning the variation of luminous flux and chromaticity of the light output. The inputs to the Monte Carlo simulation, are variations of the LED peak wavelength, the LED rated luminous flux bin, the influence of the operating conditions, ambient temperature, driving current, and the spectral response of the colour sensor. The system performance is investigated by evaluating the outputs from the Monte Carlo simulation. The outputs show that the applied control system yields an uncertainty on the luminous flux of 2.5% within a 95% coverage interval which is a significant reduction from the 8% of the uncontrolled system. A corresponding uncertainty reduction in Δu’v’ is achieved from an average of 0.0193 to 0.00125 within 95% coverage range after using the control system.

Phosphor converted laser diode light source for endoscopic diagnostics

In order to provide light sources for endourology and on-site testing of the light source, we are developing a portable endoscope light source prototype based on a phosphor converted laser diode. A small emitting area from the phosphor material excited by a laser diode enables coupling of the generated white light into thin optical fibres. The development involves designing optics for optimizing the light extraction efficiency and guiding of light to the area of interest. In this paper we compared the developed light source to the current standard in endoscopy – xenon arc lamps. Detailed spectral analysis of illuminance, CRI and CCT at two power levels and two distances for both the PC-LD and the xenon light source was performed. The obtained results verified that the developed light source is suitable for endoscopy illumination and the first pre-clinical trials will be performed shortly.
Highly efficient endoscopic white light sources may be enabled by use of phosphor converted blue laser diodes. This light source offers the advantages of a more compact and ergonomic design, lower cost, possibility of tailoring the spectral content and more uniform illumination in comparison with current technology, as well as providing the possibility of shadow formation within the operative field.

Photometric and Colorimetric Comparison of HDR and Spectrally Resolved Rendering Images

In this paper, we will demonstrate a comparison between measured colorimetric images, and simulated images from a physics based rendering engine. The colorimetric images are high dynamic range (HDR) and taken with a luminance and colour camera mounted on a goniometer. For the comparison, we have used a scene similar to the cornel box (CUPCG, 1998) but with a spectrally controllable LED light source, neutral grey walls and a colour checker board for colorimetric assessments. The luminance value and colour information of the HDR camera and rendering images are used for the comparison. The spectral irradiances of the light source were measured for two lighting scenarios: low and high correlated colour temperature (CCT) white lighting conditions for the modelling of the light source. Based on these measurements, we have conducted spectrally resolved renderings with a spectral renderer, Ocean. The colour differences between the camera and rendered images were calculated with the most recent CIE metric, CIEDE2000 (CIE, 2012). Our simulations have demonstrated interesting results, which confirm the accuracy of the Ocean engine. In the future, we want to consider non-Lambertian surfaces.

Our simulations have demonstrated interesting results, which confirm the accuracy of the Ocean engine. In the future, we want to consider non-Lambertian surfaces.
A comparison of goniophotometric measurement facilities.

In this paper, we present the preliminary results of a comparison between widely different goniophotometric and goniorspectroradiometric measurement facilities. The objective of the comparison is to increase consistency and clarify the capabilities among Danish test laboratories. The study will seek to find the degree of equivalence between the various facilities and methods. The collected data is compared by using a three-way variation of principal component analysis, which is well suited for modelling large sets of correlated data. This method drastically decreases the number of numerical values needed to represent the data. The model shows good agreement with data, while also highlighting the differences between the measurements. We conclude that the method could be useful for comparing large sets of goniophotometric data.

Angle Resolved Performance Measurements on PV Glass and Modules.
The angular response of PV-modules has significant impact on the energy production. This is especially pronounced in BIPV where installation angles often are far from optimal. Nevertheless, a gain in energy yield may be obtained by choosing a proper glass as superstrate. In this work we present the concept of PV balconies as cost efficient and easy way of integrating PV into buildings. The experimental work consists of the fabrication of single cell mini modules with different glass covering, and characterizing their angular response in a custom made setup, where only the direct sunlight is used as a light source. As a special case we estimate the annual yield for each glass in the case of PV balconies for a specific geographical location and orientation of the module.

OLEDs used in solar powered lighting applications is a market of the future. This paper reports the development of electronic Three-Port-Converters for PV OLED product integration in the low-power area respectively for 1-10 Wp and 10-50 Wp with a peak efficiency of 97% at 1.8 W of PV power for the 10 Wp version. Furthermore, we present measurements of state-of-the-art commercial available OLED with regards to the luminous flux, luminous efficacy, luminance homogeneity, temperature dependency and IV characteristic of the OLED panels. In addition, solar powered OLED product concepts are proposed.

A color management system for multi-colored LED lighting.
A new color control system is described and implemented for a five–color LED light engine, covering a wide white gamut. The system combines a new way of using pre-calibrated look-up tables and a rule-based optimization of chromaticity distance from the Planckian locus with a calibrated color sensor. The color sensor monitors the chromaticity of the mixed light providing the correction factor for the current driver by using the generated look-up table. The long term stability and accuracy of the system will be experimentally investigated with target tolerance within a circle radius 0.0011 in the uniform chromaticity diagram (CIE 1976)

Analysis of compact and portable goniospectrometer system for test of LED lamps

An experimental investigation of a compact and portable goniospectrometer system is described. Measurements are performed in two very different conditions, in a normal office environment and in a photometry laboratory under standard environmental conditions and both are compared to reference measurements in a near-field goniophotometer. A collection of six different types of directional and non-directional integrated LED lamps with three samples of each were used as test devices. It is shown that the main uncertainty comes from the inadequate thermal stabilisation of the LED lamps. With pre-heating relative differences for total luminous flux of ±2.5% were obtained. Reliable photometric data can be obtained for use in market monitoring to identify probable non-compliance LED lamps and hence as an improved method for selecting LED lamps for accredited verification testing.

A new self-made digital slide scanner and microscope for imaging and quantification of fluorescent microspheres

Objective: A low-cost microscope slide scanner was constructed for the purpose of digital imaging of newborn piglet brain tissue and to quantify fluorescent microspheres in tissue. Methods: Using a standard digital single-lens reflex (DSLR) camera, fluorescent imaging of newborn piglet brain tissue was performed. A computer algorithm available for download was created to detect fluorescent microspheres in the brain tissue slides and to calculate regional cerebral blood flow (rCBF). The precision of the algorithm was tested by comparing with manual counting of the fluorescent microspheres. Finally, bright-field imaging was tested by adding light diffuser film. Results: Cost of the slide scanner was a fraction of the cost of a commercial slide scanner. The slide scanner was able to image a large number of tissue slides in a...
semiautomatic manner and provided a large field of view (FOV) of 101 mm² combined with a resolution of 2.9 µm. The mean difference (SD) between manual and automatic counts was in absolute numbers 0.32 (1.5) microspheres ranging from -5 to 5 microspheres per slide. The relative total difference between automatic and manual counts was -3.1%.

Conclusions: A slide scanner was constructed and an automatic algorithm to detect fluorescent microspheres in tissue was developed and validated and showed an acceptable difference to "gold standard" manual counting. The slide scanner can be regarded as a low-cost alternative for researchers when digital slide imaging and quantification of fluorescent microspheres are needed.

A white–cyan-red LED system for low correlated colour temperature lighting
A white LED complemented by cyan and red LEDs is a good candidate for achieving high colour rendering at low correlated colour temperatures. This is usually very difficult with commercially available white LEDs. In addition, the system is able to replace incandescent lighting in many applications; for example, the lighting for museum display cases. To investigate and optimize the colour and light distribution properties, both spectral and geometrical modelling are used. Mapping of the possible combinations of LEDs is used to locate the optimal solutions within the colour gamut, with emphasis on chromaticity and colour rendering indices. A geometric optical model is used to design and optimize the
homogeneity of the colour and light intensity distribution as a function of angle. The resulting system produces diffused homogeneous white light with a tunable correlated colour temperature from 2000 K to 2400 K. Within this range the white light is characterized by a high general colour rendering index ($R_a > 90$), special colour rendering indices for saturated red objects ($R_9 > 85$), and low chromaticity distance ($D_{uv}$) from the Planckian locus ($D_{uv} < 2 \times 10^{-3}$).

Facility to evaluate street lightning solutions in a realistic urban setting

This paper describes a new large scale outdoor testing facility for street lighting solutions, that has been establish in Denmark for both research and demonstration purposes. The facility is fitted with lamp posts with an array of sensors and connections to allow for monitoring and control of lighting solutions under test. Initial data suggests a 75% reduction in energy usage from use of LED luminaries combined with traffic monitoring systems could be achievable.

Goniometric characterization of LED based greenhouse lighting
This paper describes a demonstration of goniorspectroradiometry for characterizations of new light emitting diode (LED) based luminaries for enhanced photosynthesis in greenhouses. It highlights the differences between measurement of the traditional high pressure sodium (HPS) luminaries and the LED based luminaries. The LED based luminaries are compared to traditional HPS luminaries; in terms of energy efficiency with regard to the photosynthetic photon flux, and the LED luminaries were found to be more effective than the HPS luminaries.

Monte carlo analysis of multicolour LED light engine

A new Monte Carlo simulation as a tool for analysing colour feedback systems is presented here to analyse the colour uncertainties and achievable stability in a multicolour dynamic LED system. The Monte Carlo analysis presented here is based on an experimental investigation of a multicolour LED light engine designed for white tuneable studio lighting. The measured sensitivities to the various factors influencing the colour uncertainty for similar system are incorporated. The method aims to provide uncertainties in the achievable chromaticity coordinates as output over the tuneable range, e.g. expressed in correlated colour temperature (CCT) and chromaticity distance from Planckian locus (Duv), and colour rendering indices (CRIs) for that dynamic system. Data for the uncertainty in chromaticity is analysed in the u’, v’ (Uniform Chromaticity Scale Diagram) for light output by comparing the variations in chromaticity differences with the “n – step u’ v’ circles” as defined in CIE TN001:2014.

Comparison of stray light in spectrometer systems using a low cost monochromatic light source

We present an experimental setup that is under development for automated stray light characterization of spectrometers. The setup uses a tuneable monochromator which enables this characterization on relatively cost low equipment. We present the measured line spread functions for two spectrometers, one low-end and one mid-range.

Spectroradiometry, Line spread functions, Stray light correction
The objectives of this work is to develop a task light for office lighting that fulfils the minimum requirements of the European standard EN12464 - 1: Light and lighting – Lighting of work places, Part 1: Indoor workplaces and the Danish standard DS 700: Lys og belysning i arbejdsmiljø, or more specifically the requirements that apply to the work area and the immediate surrounding area. By providing a task light that fulfils the requirements for task lighting and the immediate surrounding area, the general lighting only needs to provide the illuminance levels required for background lighting and thereby a reduction in installed power for general lighting of about 40% compared to the way illuminance levels are designed in an office environment in Denmark today. This lighting strategy is useful when the placement of the task area is not defined in the space before the lighting is design ed and the strategy also allows for the task area to be redefined in the space. The task lighting follows the task area as the developed task light is designed to be placed on the desktop of an office desk. The work carried out within this project is the architectural design of the task light, the optical design of the light distribution, prototype production and user tests for comparison between the prototype and traditional task lighting luminaires. The architectural design and user friendliness of the task light was a high priority within the project in order to promote market penetration of such a product. The height of the lamp head is aligned with respect to distribution and glare, which are two conflicting parameters. The broad distribution of the light requires a flat lamp head with the light source close to the bottom edge, while the desire to minimize glare is met by raising the lamp head and placing the light source as far from the bottom edge as possible. The main results of the project show opportunities for energy savings in an office environment by reducing the installed power for the general lighting by applying a task light with a wide light distribution across the desk area, providing high illuminance uniformity. There is still work to be done on the prototype to optimize the energy consumption of the task light and measures need to be taken to minimize glare from the task light as well as reflected glare. The lamp head adjustment possibilities regarding tilting and turning result in problems with glare and these adjustment possibilities should be eliminated in the final product. In general, the adjustment possibilities for height, length ways and sideways are important aspects for task lights, however they become less important when the light distribution is as wide as for the prototype. Using only standard components in the prototype, the optimal light distribution for the purpose of meeting the requirements could not be obtained. The light distribution was approximated to the requirements by using combinations of different beam shaping lenses. A final product would benefit from custom made lenses, capable of providing the desired light distribution. The user test shows that when working with general light of 100 lx in the room the developed task light with its wide light distribution provides flexibility in choosing a reading task area on the desk and provides more visibility to all objects on the desk than the two traditional reference task lights with
LED retrofit light bulbs. By utilising this new type of task light, the energy consumption by general lighting can be reduced by approximately 40% by fully exploiting the lower illuminance levels required by lighting standards for the background lighting. The energy consumption of the task lights should be optimized for a wide light distribution while minimizing problems with glare.

**Luminous flux and colour maintenance investigation of integrated LED lamps**
This article will present an investigation of the luminous flux and colour maintenance of white LED based retrofit lamps. The study includes 23 different types of integrated LED lamps, covering 18 directional and 5 non-directional. Luminous flux and colour data for operation up to 20000 h has been measured, and will be presented. Data for the first 6000 h of operation is used for studying extrapolation method and results are compared with experimental data for operation over 19000 h. It has been further examined when catastrophic failures occurred.

Comparison of user satisfaction with four different lighting concepts

This study aims at comparing user satisfaction for different lighting concepts in an office environment. The lighting concepts being compared are a conventional static lighting concept from ceiling mounted luminaires against three different types of dynamic task lighting concepts, the first providing occupant controlled task illuminance, the second concept providing occupant controlled CCT and the third providing automatically controlled CCT. Another aim is to identify which of the four lighting concepts is rated as most preferred by the test subjects. Subjects tested all four lighting concepts and questionnaires were used for rating of the concepts. Adjustable CCT of the task light was the most preferred lighting concept followed by adjustable task illuminance. Automatically controlled task CCT and conventional lighting were the least preferred. User satisfaction ratings for the lighting concepts are in the following order; Adjustable task CCT, adjustable task illuminance, automatic control of task CCT and conventional lighting.
CopenHybrid – Development of a CO2 neutral hybrid street lighting system for the Danish municipalities' illumination classes

In the present work a group of the leading researchers in Wind Energy, Solar Energy, LED and optics in Denmark have been working together with the relevant industrial technology partners and a wide range of the Danish municipalities with Gate 21 and Copenhagen Municipality in front to investigate the potential for use of hybrid street lighting in the Danish illumination classes in the municipalities and develop a specialized solution based on the specific needs of the municipalities.

A mathematical model has been developed for the energy system of the hybrid street lighting making it possible to simulate a given configuration (solar panel performance data, size and orientation - wind turbine performance data, projected area and height - battery data) over a year in an urban environment of a given configuration based on measured wind/solar/temperature data from nearby meteorological station or other relevant weather data. The simulation can show if it is possible to cover the consumption by the light source over the year. The model can be used to evaluate both commercial hybrid systems and to dimension new systems for use in given environments where the weather data are known. Since weather and day/night length are varying a lot around the world the systems should be dimensioned very differently depending on the place of use. By using the simulation tool it is shown that it is possible to create a hybrid street lighting for an urban environment with a maximum of 2 floor height buildings which governs >70% of the luminaires in Copenhagen (the Capital of Denmark) fulfilling the requirements of 2.5 lux on the street over the year. Furthermore the tool is powerful to evaluate hybrid systems on the market (if all the technical data is known) for use in a given urban environment.
Dynamic miniature lighting system with low correlated colour temperature and high colour rendering index for museum lighting of fragile artefacts

Illumination of fragile and irreplaceable historical objects exhibited to the public presents challenges with regards to: good colour rendering, low photochemical degradation of sensitive materials and general energy consumption. We present a dynamic tri-colour LED lighting system for illumination of historical artefacts in display cases at museums and other exhibitions, which can replace 3-5 Watt incandescent light bulbs with a correlated colour temperature (CCT) from 2000 K to 2400 K. The solution decreases the energy consumption by up to 80 %, while maintaining colour rendering indices (Ra) above 90 and important special colour rendering indices R9 between 50 and 90, while decreasing the level of harmful short wavelength radiation by between 20 - 30 %.

Kombineret dagslys og intelligent LED belysning - få dagslys ind i bygningerne: Slutrapport for PSO 342-044 og PSO 344-007
This report contains a description of the work carried out and the results of the research and development project "Combined daylight and Intelligent LED lighting - getting the daylight into the buildings" and form the final report for this project.
The project is carried out in cooperation between the following partners: DTU Fotonik, Statens Byggeforsknings-institut, Rambøll Danmark, Energrådgivener and Philips Lighting Denmark. The project has been led by DTU Fotonik, Senior scientist, Ph.d. Carsten Dam-Hansen.
The project was financed by the Danish Energy Association through Elforsk’s PSO program, under actions 1. Buildings, 3. Lighting and 5. Power and control electronics. The project has no. PSO 342-044 and PSO 344-007. It was initiated in February 2010 and was ended in March 2013. In the first part of the report a short resume of the project is given, describing the background and aim of the project, the work and results together with future perspectives of the results of the project. The report contains an overview of dynamic lighting systems and a description of the development of a new intelligent dynamic lighting system based on color mixing LED technology. The system, which has been developed for research purposes, is described in the last part of the report together with a description of the research user test done with the system. Finally the work on communicating the results of the project is described.

Light quality and efficiency of consumer grade solid state lighting products

The rapid development in flux and efficiency of Light Emitting Diodes (LED) has resulted in a flooding of the lighting market with Solid State Lighting (SSL) products. Many traditional light sources can advantageously be replaced by SSL products. There are, however, large variations in the quality of these products, and some are not better than the ones they are supposed to replace. A lack of quality demands and standards makes it difficult for consumers to get an overview of the SSL products.

Here the results of a two year study investigating SSL products on the Danish market are presented. Focus has been on SSL products for replacement of incandescent lamps and halogen spotlights. The warm white light and good color rendering properties of these traditional light sources are a must for lighting in Denmark and the Nordic countries. 266 SSL replacement lamps have been tested for efficiency and light quality with respect to correlated color temperature and color rendering properties.

This shows a trade-off between high color rendering warm white light and energy efficiency. The lumen and color maintenance over time has been investigated and results for products running over 11000 h will be presented. A new internet based SSL product selection tool will be shown. Here the products can be compared on efficiency, light quality parameters, thus providing a better basis for the selection of SSL products for consumers.
In this paper, we study the origin of a strong wavelength dependence of the quantum efficiency of InP/ZnS nanocrystals. We find that while the average size of the nanocrystals increased by 50%, resulting in longer emission wavelength, the quantum efficiency drops more than one order of magnitude compared to the quantum efficiency of the small nanocrystals. By correlating this result with the time-resolved photoluminescence we find that the reduced photoluminescence efficiency is caused by a fast growing fraction of non-emissive nanocrystals while the quality of the nanocrystals that emit light is similar for all samples. Transmission electron microscopy reveals the polycrystalline nature of many of the large nanocrystals, pointing to the grain boundaries as one possible site for the photoluminescence quenching defects.
Simulation Tool for Designing off-Grid PV Applications for the Urban Environments

A barrier for exploiting use of standalone solar lighting for the urban environment seem to be lack of knowledge and lack of available tools for proper dimensioning. In this work, the first part of the development of powerful dimensioning tool is described and initial measurements are presented.

User evaluation of eight led light sources with different special colour rendering indices R9
In this study we evaluated the influence of the special colour rendering index R9 on subjective red colour perception and Caucasian skin appearance among untrained test subjects. The light sources tested are commercially available LED based light sources with similar correlated colour temperature and general colour rendering index, but with varying R9. It was found that the test subjects in general are more positive towards light sources with higher R9. The shift from a majority of negative responses to a majority of positive responses is found to occur at R9 values of ~20.

Wind Turbines on CO2 Neutral Luminaries in Urban Areas

In the present work, an overview of three different wind turbines used in hybrid luminaries is presented. The turbines are: vertical-axis twisted Savonius, three-blade horizontal-axis, and vertical-axis three-blade helical H-rotor. The considered luminaries are also equipped with photovoltaic panels and batteries, detailed investigation of which is outside the scope of the present manuscript. Analysis of the turbines' performance based on producer-supplied power curves is presented together with an estimation of the wind climate in Copenhagen district comprising 1-2 story single family buildings. A new vertical-axis twisted Savonius rotor is proposed for a luminary being designed for such a district within the “Development of CO2 neutral urban luminary” project.

Museum lighting for golden artifacts, with low correlated color temperature, high color uniformity and high color rendering index, using diffusing color mixing of red, cyan, and white-light-emitting diodes

Museum lighting presents challenges mainly due to the demand for precise color rendering and the damaging effects of radiation. Golden objects must normally be illuminated by the non-standard CCT of 2200 K. An LED system that conforms to these requirements has been developed and implemented at the Royal Danish Collection at Rosenborg Castle. Color mixing of red, cyan, and white LEDs was employed to achieve the spectral power distribution needed for the required CCT and a CRI above 90. Color uniformity is achieved by the use of a highly diffusing reflector. The system has shown energy saving above 70%.

Museum lighting for golden artifacts, with low correlated color temperature, high color uniformity and high color rendering index, using diffusing color mixing of red, cyan, and white-light-emitting diodes

Optimization of light quality from color mixing light-emitting diode systems for general lighting

To address the problem of spectral light quality from color mixing light-emitting diode systems, a method for optimizing the spectral output of multicolor LED system with regards to standardized quality parameters has been developed. The composite spectral power distribution from the LEDs are simulated using radiometrically measured single LED spectra. The method uses electrical input powers as input parameters and optimizes the resulting spectral power distribution with regard to color rendering index, correlated color temperature and chromaticity distance. The results indicate Pareto optimal boundaries mapping the capabilities of the simulated lighting system.

Characterization, Modeling, and Optimization of Light-Emitting Diode Systems

This thesis explores, characterization, modeling, and optimization of light-emitting diodes (LED) for general illumination. An automated setup has been developed for spectral radiometric characterization of LED components with precise control.
of the settings of forward current and operating temperature. The automated setup has been used to characterize commercial LED components with respect to multiple settings. It is shown that the droop in quantum efficiency can be approximated by a simple parabolic function. The investigated models of the spectral power distributions (SPD) from LEDs are the strictly empirical single and double Gaussian functions, and a semi empirical model using quasi Fermi levels and other basic solid state principles. The models are fitted to measured SPDs, using the free parameters. The result show a high correlation between the measured LED SPD and the fitted models. When comparing the chromaticity of the measured SPD with fitted models, the deviation is found to be larger than the lower limit of human color perception. A method has been developed to optimize multicolored cluster LED systems with respect to light quality, using multi objective optimization. The results are simulated SPDs similar to traditional light sources, and with high light quality. As part of this work the techniques have been applied in practical illumination applications. The presented examples are historical artifacts and illumination of plants to increase photosynthesis.

Spectral design of new dynamic LED light sources

The use of LED technology in lighting applications, termed Solid State Lighting, is increasing drastically these years due to increasing flux and efficiency of LED components. The advantages of using Solid State Lighting is not only energy savings but the possibility to create new dynamic light sources that can be varied in color temperature and achieving color rendering properties. New LED light sources are constructed as clusters of colored LEDs. Modeling and optimization of the control of the light from the individual LEDs is a necessity for the desired operation of the new dynamic light source. Detailed knowledge of the spectral power distribution as a function of operating current and temperature is required for the modeling and optimization. Examples of new high color quality dynamic white light sources that can be tuned from warm white light at 2700 K to cold white light at 6500 K are presented.

Slutrapport for ELFORSK projekt nr. 341-009, Den CO2 neutrale arbejdsplads – hovedprojekt

As the world develops, the requirement for more electrical equipment in everyday life is increasing rapidly. The power consumption of electrical appliances both in operation and in standby mode therefore greatly contributes to our total energy consumption. When regarding the energy lifetime of an electrical product, the amount of energy used for standby cannot be neglected and will in many cases exceed the power used in operation. The potential of PV’s used indoor to supply the standby power is a fairy unexploited field, but can have a revolutionary effect on the total energy consumption worldwide. This paper presents the results gained in the ongoing project ‘The CO2 neutral work space’, which was started up in 2008. The objective of the project is focused on elucidating and uncovering the great potential for usage of PV’s in indoor applications to power the standby electricity consumption. To integrate solar cells into a design object has proved to be challenging. Throughout the development process it has been extremely important with the coherence between technology and design in a close dialogue between all parties. The project team has made three distinctive designs, where design solutions are created in cooperation between the PV-technology and a user-friendly approach based on the observations the secretaries have shown that the desk is often covered by electronic devices and paper material. The final three design concepts adapt to Montanas existing aesthetics and design as a transparent screen, a desk integration and a flexible solution. All three design concepts are displayed in either 1:1 or functioning prototypes, depending on allowance and performance in the chosen PV-technologies. The prototypes have been shown at various design shows and scientific conferences internationally and nationally. A LED based solar simulator has been build and follows the IEC904-9 requirements for a Class A solar simulator though at an irradiation level of about 100 W/m2. It is more advanced and flexible than traditional artificial sun simulators based on a Xenon light source since because of the flexibility in light spectrum and intensity made available by the LED setup. The system has been tested on several solar cells and panels for IV characterization and obtaining the spectral response of cells at different levels of irradiation.

Slutrapport for Implementering af energibesparelser ved benyttelse af højkvalitets LED belysning PSO 339-025

This report describes the research and development project “Energysavings by implementation of high quality LED illumin ation”. The project is carried out in cooperation between DTU Fotonik, Teknologisk Institut, De Danske Kongers
Kronologiske Samling (DKKS), Lumodan, Osram, Thermex and DONG Energy, headed by Carsten Dam-Hansen, DTU Fotonik. The project is financed by the Danish Energy Association through Elforsk’s PSO program, under 3a. LED illumination. The project has no. PSO 339-025 and was initiated in February 2007 and was ended in March 2010. The first part of the report describes the background and aim of the project, the work and results together with future perspectives of the results of the project. The report further contains two sections about the work on design and development of two new energy efficient and high quality LED illumination systems for display case and cooker hood illumination. Finally the work on communicating the results of the project is described.

Characterization of a magnetic trap by polarization dependent Zeeman spectroscopy

This paper demonstrates a detailed experimental study of our cloverleaf magnetic trap for sodium atoms. By using polarization dependent Zeeman spectroscopy of our atomic beam, passing the magnetic trap region, we have determined important trap parameters such as gradients, their curvatures and corresponding trap frequencies. Experimental findings are compared to theoretical calculations as well as complementary methods of characterizing the trap.

Projects:

Laser-driven white light source employing fluorescent silicon carbide (LASIC)
Light-emitting diode-based white light sources are penetrating into the lighting market thanks to its energy efficiency. However, the brightness of such light source is limited by the droop effect, triggering exploration in the laser-driven white lighting because lasers have even higher efficiency without droop effect in addition to the compact size and small spot size. In this project, a new type of wavelength conversion material i.e. fluorescent silicon carbide (f-SiC) is explored as a laser-driven white light source, aiming to provide a better solution than the commercial phosphor solution in terms of brightness, thermal conductivity, and lifetime.

Energy Efficient Laser Enhancement of Stage Spotlights
The project aims at bringing novel energy efficient laser lighting technology to the entertainment lighting industry by developing and demonstrating two new types of laser based light engines. They are designed to replace high intensity discharge (HiD) lamps used in high power stage spot lamps, leading to significant reductions in energy consumption and dramatic increase in lamp lifetime and reduction of the environmental impact. This cannot be achieved using Light emitting diode (LED) technology alone, due to the limited luminance of LEDs.

The project team unifies all the necessary competences and experimental facilities to the project work from laser diode and LED systems, spectroradiometric testing, materials handling, thermal management, product design and production, electronic control to market/user knowledge within the entertainment lighting industry.
The project will bring the two companies in front within laser lighting technology and many new applications are anticipated within the lighting industry. The general perspectives and results of the development work will be made publically available, e.g. to the scientific and industrial communities.

Project

**EMPIR 15SIB07 PhotoLED, Future photometry based on solid-state lighting products**

Solid-state lighting, which uses light-emitting diodes (LEDs), is globally replacing traditional incandescent lighting, due to lower power consumption and greater durability. Photometers are used to measure the performance of lights, and are calibrated using standard lamps to ensure the accuracy and consistency of measurements. However, the standard lamps used for calibration are currently based on incandescent lights, not LEDs. This project will develop new standard lamps based on LEDs and new measurement techniques for defining the properties of solid-state lights. The results will be used by National Measurement Institutes and test laboratories to accurately calibrate solid-state light photometers and will give European industry an advantage in the development of new commercial standard lamps. These outputs will result in a more reliable classification of the energy efficiency of solid-state lighting, increasing consumer confidence in this new greener technology.

Project

Warm or Cold, Lights influence on thermal comfort
Various indicators point out that a connection exists between the ambient temperature and the correlated color temperature that users prefer for the lit environment. In warm climate the use of cooler lighting is much more common than in a colder climate where people use much warmer light sources. Presumably the use of different colored light sources is due to the experience of cooler climate at cooler light sources and the impression of warmth follows a warmer looking light source. With new LED technology the correlated color temperature (warm white to cool white) is easily controllable.

The goal of the project is to demonstrate how controllable LED lighting can be used to expand the temperature interval that users find comfortable. The project is founded on previous research on colored light. It will lead to a decrease in the energy consumption of buildings.

**Daylight as a Driver for Healthier Energy Optimization**
Renovations of existing buildings have primarily focused on the energy consumption and thermal comfort. This project involves health as a priority design parameter, and through an exemplary case study, the project examines how essential health aspects are better served. The project focuses on facade design. The project involves daylight quality as a design parameter and focuses on the clearest glass quality on the market. Through a major housing, the study documents how aspects of health and energy are influenced by the quality of daylight/glass quality.

Global Test of SSL Products - IEA-4E-SSL

The purpose of the project is to actively utilize the national expertise on LED technology and Solid State Lighting (SSL) and the new test facilities, which were established as a part of a global network of test laboratories, in the continued international collaboration under the IEA 4E-SSL Annex. The member countries, including Denmark, have chosen to continue the work, which is still highly relevant in a fast growing global market of SSL products. The aim of the SSL Annex is to assist member governments in promoting SSL rapidly as an effective means to reduce energy consumption worldwide. In the SSL Annex this will be done through recommendations for performance tiers, evaluation of test methods and test laboratories, SSL product benchmarking, and new tools for SSL market monitoring and control.

Solar powered OLED solutions for the urban environment

OLED technology is seen by many as one of the competitors to the inorganic LED technology, which is starting to dominate the lighting market these days. The material forming the active part (light source) in the OLED is based on organic dyes, which basically are very cheap and are compatible with inkjet and other printing technologies that make the possibilities of how to think light sources in the future endless.

The OLED technology is in a significantly less mature stage of development than the inorganic LED variant and it is in a rather far future that we will see OLEDs become a competitive source for the mass market taking over from the LED. So in the beginning, the OLED industry agrees that the market penetration must be based on niche applications which are less price sensitive than standard light sources. In this project we use OLED technology’s unique capabilities as transparent light source having a very high energy efficiency and light quality in combination with solar cells capable of creating efficient autonomous lighting products to the urban space. Furthermore, OLEDs can be realized in a pixelated configuration so that each pixel can be ad-dressed separately e.g., RGB, providing entirely new opportunities for communicating light sources.

The project seeks further to address and lowers the barriers for the use of OLED lighting which is in a phase where producers lack the specific applications to come to market with their prod-ucts, which is something we are known for being excellent at in Denmark.

Project

CooLED - a new generation LED light source for the timeless high-end market.
The project aims to develop and demonstrate an optical flexible LED bulb using the energy efficient technology of LEDs optimally when applying it to the timeless exclusive classical lamps such as the PH5 by Poul Henningsen, the Flowerpot and the Globe by Verner Panton etc. When inserting traditional LED light sources in these lamps most of the energy is deposited in the lamps' shade units due to the way the light source emits its light. By directing the light correctly out through the lamp shade it is possible to gain up to 90 % in energy reduction.
Due to a new and highly innovative thermal management design separating the LEDs from the transformer electronics it is possible to minimize the changing cost of the light source due to the improved longevity.

The thermal management design is made possible by the use of piezoelectric transformer technology converting 40W/cm² with 98% efficiency making it geometrically possible to fit in the socket.

The outcome of this project will settle with the increase of light sources by introducing an optically flexible retrofit LED solution. By applying low cost, tailored lenses that are interchangeable this solution could give the light a geometrical suitability for the application at hand.

Project

Smart Grid Ready Energy Efficient Lighting System for Green House Horticulture

The project aims to develop an energy-cost-effective artificial light management system, which optimizes plant growth in relation to energy costs and also integrates greenhouse horticulture with the grid through DONG Energy's Power Hub concept, which enables the growers to deliver GRID-system performance by dynamically regulate their consumption. This is part of a joint proposal for GUDP and EUDP.

Combined daylight and intelligent LED lighting: Getting the daylight into the buildings
The project aims to develop and demonstrate a new concept of intelligent LED lighting which complements and follows the rhythm of daylight and thus bringing ‘daylight’ into buildings. It is based on LED technology’s unique color characteristics and high efficiency, allowing a concept which provides both high-quality lighting and can be energy saving. New LED lighting systems and combined with a new color sensor system for control are developed. LED light source placement and control strategies are analyzed and optimized through model calculations that include the daylight contribution. User experience of the concept will be examined through demonstration setups and the potential energy savings specified through measurements on these setups.

Project
LED lighting quality program
The aim of the project is to establish a quality program for LED lighting products available on the Danish market, with focus on light quality and energy consumption. A transparent overview of the products, price, light quality and energy efficiency will be the result and thus providing a better basis for the selection of products for professional buyers, as well as ordinary consumers. The project will: - Define relevant quality parameters of LED lighting products, including introducing understandable labels - Provide measurement facilities and develop procedures for the measurement of quality parameters - Establish a quality program of selected groups of LED lighting products with a categorization of quality parameters and price - Communicate knowledge on LED lighting products - Participate in international standardization of the test and characterization of LED light sources. The project will result in the construction of a self-sustaining quality program for LED lighting products that go beyond the project period.

**Description**
LED Reference Spectrum for Photometer Calibration

The purpose of this TC is to investigate and publish an LED Reference spectrum to complement the Standard Illuminant A. The TC will investigate and decide the spectral shape, wavelength range and the format to be used for publishing the reference spectrum. In addition a metric for the quality of the match of spectral distribution of real sources to the reference spectrum will be defined for the purpose of photometric calibrations.

Description
Electroluminescence (EL) imaging can be used to quickly and accurately detect a large range of major and minor faults in PV modules. For EL inspections of PV power plants, the fastest scenario will include a drone based image acquisition in continuous movement. With this motivation, in this work we investigate the quality of EL images acquired under different movement speeds and frame rate scenarios.

CIE Tutorial and Expert Symposium on Measurement Uncertainties in Photometry and Radiometry for Industry
Period: 9 Sep 2014 → 10 Sep 2014
Anders Thorseth (Participant)
Department of Photonics Engineering
Diode Lasers and LED Systems

Description
CIE offers a one-day tutorial on measurement uncertainty concepts in photometry and radiometry. Invited experts will present lectures from basic concepts to advanced techniques in photometric and colorimetric measurements, aimed at engineers, testing-laboratory staff and researchers in LED and solid state lighting measurement and other fields. Special emphasis is given to applied concepts.

On the following day, a scientific symposium will feature contributed papers.

The event is organized by CIE Division 2. It will be held in conjunction with meetings of several Technical Committees of CIE Division 2 (Sept 9-10, 2014)

2nd Annual Workshop on Research and Development of Light-Emitting Diodes
Period: 15 Mar 2013
Anders Thorseth (Speaker)
Department of Photonics Engineering
Diode Lasers and LED Systems

Description
The rapid development in flux and efficiency of Light Emitting Diodes (LED) has resulted in a flooding of the lighting market with Solid State Lighting (SSL) products. Many traditional light sources can advantageously be replaced by these SSL retrofit products. There are however large variations in the quality of the available products, and some are not better than the ones they are supposed to replace. Here the results of a two year study investigating SSL products on the Danish market are presented. The light sources have been tested for luminous flux and spectral power distribution. Focus has been on SSL products for replacement of incandescent lamps and halogen spotlights. More than 300 SSL replacement lamps have been tested for efficiency and light quality with respect to correlated color temperature and color rendering properties. The warm white light and good color rendering properties of these traditional light sources are a must for lighting in Denmark and the Nordic countries. We compare the test results with the requirements in the EU LED quality charter, and find many products with light inferior light quality and efficiency. The lumen and color maintenance over time has been investigated by non-accelerated lifetime tests and results for products running over 8000 h will be presented. A new internet based SSL product selection tool will be shown. Here the products can be compared on efficiency, light quality parameters and price, thus providing a better basis for the selection of SSL products for consumers.

Meijo-DTU workshop on research and development of light-emitting diodes
Period: 22 Mar 2012
Anders Thorseth (Participant)
Department of Photonics Engineering
Diode Lasers and LED Systems

Description
Program
9:00~9:15
Introduction
Haiyan Ou, DTU
9:15~9:45
LED innovation at DTU Fotonik
Paul Michael Petersen, DTU
9:45~10:15
Physics of fluorescent SiC for white LED application
Prof. Satoshi Kamiyama, Meijo
10:15~10:45
Nitride-based-semiconductors research at Meijo University
Prof. Motoaki Iwaya, Meijo
10:45~11:15
Coffee break and discussion
11:15~11:45
Observation of GaInN strain relaxation using in situ X-ray diffraction monitoring during metalorganic apour phase epitaxy growth
Dr. Daisuke Iida, Meijo
1145~12:15
Diffractive effects of periodic plasmonic structures on the light emitting diode
Yuntian Chen, DTU
12:15~13:15
Lunch
13:15~13:45
Nanostructuring on fluorescent SiC for the luminescence enhancement
Yiyu Ou, DTU
13:45~14:15
Characterization and optimization of LED systems
Anders Thorseth, DTU
14:15~14:45
Spectral design flexibility of LEDs bring better life
Haiyan Ou, DTU
14:45~15:15
Coffee break and discussion
15:15~17:00
Lab and cleanroom tour

Description
An automated setup has been developed for spectral radiometric characterization of LED components with precise control of the settings of forward current and operating temperature. The automated setup has been used to characterize commercial LED components with respect to multiple settings. It is shown that the droop in quantum efficiency can be approximated by a simple parabolic function. The investigated models of the spectral power distributions (SPD) from LEDs are the strictly empirical single and double Gaussian functions, and a semi empirical model using quasi Fermi levels and other basic solid state principles. The models are fitted to measured SPDs, using the free parameters. The result show a high correlation between the measured LED SPD and the fitted models. When comparing the chromaticity of the measured SPD with fitted models, the deviation is found to be larger than the lower limit of human color perception. A method has been developed to optimize multicolored cluster LED systems with respect to light quality, using multi objective optimization.

The results are simulated SPDs similar to traditional light sources, and with high light quality. As part of this work the techniques have been applied in practical illumination applications. The presented examples are historical artifacts and illumination of plants to increase photosynthesis.

SPIE 2013 Green Photonics Award for Solid State Lighting and Displays
Carsten Dam-Hansen (Recipient), Dennis Dan Corell (Recipient), Anders Thorseth (Recipient) & Peter Behrensordoef Poulsen (Recipient)
Department of Photonics Engineering, Diode Lasers and LED Systems

Description
The SPIE Green Photonics Award for Solid State Lighting and Displays recognizes outstanding contributions that enable efficient new light sources that will provide long-lived and economical illumination for human activities and information display. The paper Light quality and efficiency of consumer grade solid state products is recognized for pioneering contributions in the development of advanced technologies for the possible applications in infrared excited LED, lighting, lasers and displays.
