Human MHC-II with Shared Epitope Motifs Are Optimal Epstein-Barr Virus Glycoprotein 42 Ligands—Relation to Rheumatoid Arthritis - DTU Orbit (18/03/2019)

Rheumatoid arthritis (RA) is a chronic systemic autoimmune disorder of unknown etiology, which is characterized by inflammation in the synovium and joint damage. Although the pathogenesis of RA remains to be determined, a combination of environmental (e.g., viral infections) and genetic factors influence disease onset. Especially genetic factors play a vital role in the onset of disease, as the heritability of RA is 50–60%, with the human leukocyte antigen (HLA) alleles accounting for at least 30% of the overall genetic risk. Some HLA-DR alleles encode a conserved sequence of amino acids, referred to as the shared epitope (SE) structure. By analyzing the structure of a HLA-DR molecule in complex with Epstein-Barr virus (EBV), the SE motif is suggested to play a vital role in the interaction of MHC II with the viral glycoprotein (gp) 42, an essential entry factor for EBV. EBV has been repeatedly linked to RA by several lines of evidence and, based on several findings, we suggest that EBV is able to induce the onset of RA in predisposed SE-positive individuals, by promoting entry of B-cells through direct contact between SE and gp42 in the entry complex.

General information
State: Published
Organisations: Department of Bio and Health Informatics, Integrative Systems Biology, Immunoinformatics and Machine Learning, Statens Serum Institut, Carlsberg Research Center
Contributors: Trier, N., Gonzalez-Izarzugaza, J. M., Chailyan, A., Marcatili, P., Houen, G.
Number of pages: 18
Publication date: 2018
Peer-reviewed: Yes

Publication information
Journal: International Journal of Molecular Sciences (Online)
Volume: 19
Issue number: 1
Article number: 317
ISSN (Print): 1661-6596
