An azumamide C analogue without the zinc-binding functionality†

Jesper S. Villadsen,a Betül Kitir,‡a Kathrine Wich,‡ Tina Friis,b Andreas S. Madsen‡a and Christian A. Olsen‡,∗a

Histone deacetylase (HDAC) inhibitors have attracted considerable attention due to their promise as therapeutic agents. Most HDAC inhibitors adhere to a general “cap-linker-Zn2+-binding group” architecture but recent studies have indicated that potent inhibition may be achieved without a Zn2+ -coordinating moiety. Herein, we describe the synthesis of an azumamide analogue lacking its native Zn2+-binding group and evaluation of its inhibitory activity against recombinant human HDAC1–11. Furthermore, kinetic investigation of the inhibitory mechanism of both parent natural product and synthetic analogue against HDAC3-NCoR2 is reported as well as their activity against Burkitt’s lymphoma cell proliferation.

Introduction

Histone deacetylase (HDAC) enzymes,1,2 or perhaps more appropriately termed lysine deacylases (KDACs),3–5 have attracted attention as putative therapeutic targets,6–9 especially due to their ability to modify the landscape of post-translational modifications (PTMs) on histone proteins in chromatin.6 Indeed, two HDAC inhibitors [i.e., SAHA (vorinostat, marketed as Zolinza®)10 and romidepsin (FK228, marketed as Istodax®)11] have received approval by the Food and Drug Administration in the US for treatment of cutaneous T-cell lymphoma, and several other compounds are currently in clinical trials for additional indications.12

In addition to the depsipeptide romidepsin mentioned above, Nature has provided a variety of potent macrocyclic HDAC inhibitors such as the trapoxins, apicidins, azumamides, chlamydocin, and largazole.13–15 The apicidin structure (1)16 has been the subject of numerous structure–activity relationship studies,17–24 and recently, analogues without the so-called Zn2+-binding group (the ethylketone moiety) were investigated by Ghadiri and coworkers (e.g., 2 and 3, Scheme 1).24 The Zn2+-binding side chain was substituted with various alkyl groups, and the optimal side chain at this position was a non-branched propyl group. Not surprisingly, these inhibitors were significantly less potent than their ethylketone-containing counterparts, but still exhibited Ki-values of just 30–50 nM against HDACs 1–3.24 Since a wide variety of enzymes rely on metal ions for catalytic activity, excision of the Zn2+-binding group may enable development of more selective HDAC inhibitors with fewer adverse effects.

We found this idea attractive and decided to investigate the macrocyclic core of the azumamides25–27 (4–8) in a similar fashion by synthesizing compound 9 (Scheme 1). The azumamides contain relatively weak Zn2+-binding groups (carboxylate or carboxamide)28 while still exhibiting high potency as class I HDAC inhibitors with low nanomolar Ki-values recorded for

![Scheme 1](image-url)
azumamides C (6) and E (8). Since azumamide C was slightly more potent than azumamide E, we substituted the Zn-binding side chain of the $\beta$-amino acid in compound 6 with a propyl group to give compound 9. In addition to removal of the metal-coordinating capability, removal of this negatively charged carboxylate, may furthermore improve cell permeability of the ligand. We here present the synthesis and evaluation of compound 9 as an HDAC inhibitor.

Results and discussion

Chemistry

The three $\beta$-amino acids necessary to prepare compound 9 were purchased and the $\beta$-amino acid building block (14, Scheme 2) was prepared using chiral sulfanylminol 12, which was obtained by condensation of butanal (10) and (S)-2-methylpropane-2-sulfinamide ("Ellman’s auxiliary", 11). The diastereoselective Mannich reaction between imine (12) and the Z-enolate of tert-butyl propionate provided the (2S,3R)$\beta$-amino ester (13) as the major diastereoisomer. Acid mediated cleavage of the tert-butyl ester and the sulfanyl group with both TFA and HCl to ensure full conversion, afforded the fully deprotected $\beta$-amino acid and subsequent treatment with Fmoc-OSu furnished the desired $\beta$-amino acid building block (14).

Unfortunately, we were unable to obtain crystals for determination of the absolute stereochemistry by X-ray crystallography. Thus, the stereochemistry was instead confirmed by conversion of sulfanyl-protected tert-butyl ester 13 to the previously reported Cbz-protected methyl ester (15, Scheme 3) and both optical rotation and NMR data were in full agreement with the previously reported data (see also ESI, Table S1†).

Coupling of the $\beta$-amino acid (14) to a resin-bound tripeptide [H-$\beta$-Val-$\beta$-Ala-$\beta$-Tyr-(2-chlorotrityl-resin)] using HATU, followed by removal of the Fmoc group and cleavage from the resin afforded linear tetrapeptide 16. Macrolactamization, under dilute conditions (0.4 mM in DMF), using HATU as the coupling reagent afforded target peptide 9 (Scheme 4). The relatively low yield is similar to those previously achieved for similar compounds and may, at least in part, be attributed to poor solubility in the water-acetonitrile mobile phase used in reversed-phase HPLC purification. However, further optimization of cyclization efficiency, which is known to be notoriously troublesome for small peptides, may also prove worthwhile.

Profiling of HDAC inhibitory activity

We first screened the new compound along with a non-cyclized azumamide C analogue (for structure, see ESI, Fig. S1†) and SAHA as internal control against the full panel of recombinant human HDACs 1–11 applying a single inhibitor concentration (ESI, Fig. S1†). The linear peptide was included to address the importance of the macrocyclic nature of the azumamides and, somewhat expectedly, the linear compound was not inhibiting any of the HDACs potently. Poor inhibitory activities were also observed for macrocycle 9 against class I HDAC8, class IIa HDACs (4, 5, 7, and 9), and class IIb HDAC6, and it was therefore decided to proceed with full dose–response profiling only against HDACs 1–3, 10, and 11 (ESI, Fig. S2†).

To be able to compare potencies irrespective of applied substrate identity and concentration in the assays, we determined $K_i$-values using the Cheng–Prusoff equation and the $K_m$-values for the selected substrate–enzyme combinations (Table 1). Not surprisingly, compound 9 was less potent than its parent compound, azumamide C.

Still, compound 9 exhibited low micromolar inhibition of class I HDACs even without the ability to coordinate to Zn$^{2+}$ in the active site. Interestingly, the edited analogue (9) was either equipotent or slightly more potent than the corresponding carboxamide-containing natural product azumamide B (Table 1 and ESI, Fig. S2†). The azumamide core, however, could not compete with the most potent compounds from the more elaborate series.

of cyclotetrapeptide HDAC inhibitors without Zn\(^{2+}\)-binding groups previously reported.\(^{24}\)

**Kinetic evaluation of HDACi activity**

Since compound 9 was relatively potent against HDAC3 and since HDAC3 was the only enzyme in complex with its co-repressor,\(^{37}\) which may affect the inhibitor potency,\(^{38}\) we chose to investigate this interaction in more detail by kinetic experiments. Performing progression curve inhibition experiments where the enzymatic catalysis is followed over time in the presence of various inhibitor concentrations may reveal insights regarding the mechanism of inhibition. A recent study demonstrated a slow-binding mechanism of benzamide-based inhibitors against HDAC3-NCoR2,\(^{39}\) that would not be revealed by simple dose–response experiments performed in an endpoint fashion. We thus performed similar experiments to investigate the mechanism of inhibition exhibited by both azumamide C (6) and compound 9, with SAHA included as a control compound (Fig. 1).

In all cases, the linear progression curves revealed a constant rate of substrate conversion over time, which indicate a standard fast-on–fast-off mechanism of inhibition. This is in agreement with previous findings for SAHA\(^{39}\) and non-Zn\(^{2+}\)-binding macrocycles,\(^{24}\) but to the best of our knowledge, this is the first investigation of the mechanism of inhibition by azumamide natural products.

The \(K_{i}\)-values derived from fitting the continuous assay data were generally 2–4-fold lower than those obtained by applying the Cheng–Prusoff equation to simple dose–response results (Table 1). The respective values were in the same range, however, and the relationship between compound potencies showed the same trend. Thus, we find the dose–response/Cheng–Prusoff method to be sufficient for determination of \(K_{i}\)-values of compounds with a known fast-on–fast-off inhibition mechanism.

**Effect on cultured cancer cells**

Epigenetic silencing of the proapototic Bcl-2-family gene, Bim, in Burkitt’s lymphoma cells by concurrent promoter hypermethylation and deacetylation has been demonstrated to be involved in the mechanism underlying the common chemoresistance of Burkitt’s lymphoma. This chemoresistance has been reversed by treatment with the HDAC inhibitor SAHA.\(^{40}\) To investigate whether our compounds could influence proliferation of lymphoma cells, we tested their effect on the Epstein Barr virus (EBV)-infected human Burkitt’s lymphoma cell line, EB-3.

**Fig. 1** Progression curves and data fitting of the inhibition of HDAC3-NCoR2. Data were fitted to the equation, \(v/V_0 = (1 + [I]/(K_i(1 + [S]/K_m)))^{-1}\), using the GraphPad Prism software to derive the \(K_i\)-values shown in the figure above.
To assess the effects of azumamides B (5) and C (6) as well as compound 9 along with positive controls SAHA and apicidin, we used the MTT assay, in which cleavage of yellow MTT affords purple formazan crystals in functioning mitochondria to give a measure of cell viability. Initially, we screened all five compounds in triplicate at 10 μM and only the positive controls, SAHA and apicidin inhibited cell proliferation. We therefore tested the compounds starting at higher concentrations of the macrocycles. Since all compound stock solutions were prepared in DMSO due to solubility issues, we tested 2-fold dilutions of DMSO (from 1%) in parallel with the 2-fold serial dilutions of the compounds. Based on this, SAHA and apicidin exhibited GI50 values of 2.8 μM and 0.8 μM, respectively. For apicidin, this correlates well with values previously obtained against HeLa, Hct-116, MCF-7, KYO-1, and K-562 cells.21 The EB-3 cell proliferation was inhibited at 1% but not at 0.5% DMSO and this resulted in a maximal reliable concentration of azumamide C of 25 μM while it was 50 μM for azumamide B and 9. For all three compounds the GI50 values were deemed well above this limit as no reproducible growth inhibition was observed for any of the compounds.

Conclusions

In the present study, we have synthesized an analogue of the naturally occurring HDAC inhibitor, azumamide C, which is structurally edited to prevent coordination to the zinc ion present in the HDAC enzyme active sites. This allowed us to elucidate the binding affinity of the natural product's macrocyclic core, which proved to be in the low- to sub-micromolar range. We furthermore, showed that both natural product and its analogue inhibit HDAC3-NCoR2 via a fast-on–fast-off mechanism by performing continuous assay experiments.

Not surprisingly, this non-Zn\(^{2+}\)-binding analogue was significantly less potent than its carboxylate-containing parent compound against HDACs. However, it is quite remarkable that our synthetic analogue was at least as potent as the corresponding carboxamide-containing natural product azumamide B (5). It is puzzling that the marine sponge, from where the naturally occurring HDAC inhibitor, azumamide C, which is present in the HDAC enzyme active sites. This allowed us to elucidate the binding affinity of the general pharmacophore for HDAC inhibition, but apparently contain a redundant Zn\(^{2+}\)-binding group. We finally tested the compounds’ ability to inhibit proliferation of EB-3 cells in vitro. Contrary to both SAHA and apicidin none of the tested azumamide analogues were potent growth inhibitors, which underscores that a fine-tuned combination of HDACi potency and cell permeability is required for activity in cells.

Experimental

Synthetic procedures

\((S,E)-N\)-Butylidene-2-methylpropane-2-sulfinamide (12). A solution of butraldehyde (0.80 mL, 8.91 mmol, 2.0 equiv.) in anhydrous CH\(_2\)Cl\(_2\) (1.0 mL) was added dropwise to a solution of anhydrous CuSO\(_4\) (3.6 g, 22.6 mmol, 5.0 equiv.) and \((S)\)-2-methyl-2-propanesulfanilamide (0.54 g, 4.46 mmol) in anhydrous CH\(_2\)Cl\(_2\) (7.0 mL). After stirring vigorously for 20 hours the reaction mixture was filtered through a pad of Celite and the filter cake washed with CH\(_2\)Cl\(_2\). The combined organic phases were concentrated in vacuo and purification by vacuum silica gel chromatography afforded tert-butanesulfynil imine 12 (0.72 g, 92%) as a colorless oil. \(^1\)H NMR (300 MHz, CDCl\(_3\)) \(\delta\) 8.03 (t, \(J = 4.7\) Hz, 1H), 2.46 (td, \(J = 7.3, 4.7\) Hz, 2H), 1.63 (h, \(J = 7.4\) Hz, 2H), 1.16 (s, 9H), 0.95 (t, \(J = 7.4\) Hz, 3H); \(^{13}\)C NMR (75 MHz, CDCl\(_3\)) \(\delta\) 169.7, 56.5, 38.1, 22.5, 19.0, 13.9. Spectral data were in agreement with previously reported data.

\((2S,3R)-3\text{-Fmoc-amino-2-methylhexanoic acid} \text{-13})\. A solution of LDA (1.5 M in THF, 5.0 mL, 7.5 mmol, 2.6 equiv.) was added dropwise over 5 min to a solution of HMPA (1.5 M, 8.6 mmol, 5.7 equiv.) in dry THF (5.0 mL) at –78 °C. After 15 min, tert-butyl propane (1.1 mL, 7.3 mmol, 2.5 equiv.) was added dropwise and after stirring for additionally 30 min imine 12 (0.51 g, 2.90 mmol) in anhydrous THF (2.0 mL) was added dropwise. After 2 hours the reaction was quenched with sat. aqueous NH\(_4\)Cl and warmed to room temperature. Aqueous HCl (1 M, 20 mL) was added and the mixture extracted with EtOAc (2 × 60 mL). The combined organic phases were washed with brine (40 mL), dried (MgSO\(_4\)), filtered, and concentrated in vacuo. Diastereoselectivity was determined by \(^1\)H NMR integration of the crude reaction mixture (65 : 25 : 8 : 2). Purification by silica gel chromatography afforded \(\beta\)-amino ester 13 (335 mg, 38%) as needle-like crystals. \(^1\)H NMR (300 MHz, CDCl\(_3\)) \(\delta\) 3.52 (m, 1H), 3.13 (d, \(J = 8.1\) Hz, 1H), 2.46 (m, 1H), 1.60–1.46 (m, 3H), 1.42 (m, 10H), 1.18 (s, 9H), 1.07 (d, \(J = 7.1\) Hz, 3H), 0.91 (t, \(J = 6.9\) Hz, 3H); \(^{13}\)C NMR (75 MHz, CDCl\(_3\)) \(\delta\) 173.8, 80.7, 59.0, 56.3, 45.2, 36.6, 28.2, 22.9, 19.4, 13.9, 11.8. HRMS (ESI–TOF) calecd for C\(_{15}\)H\(_{31}\)NO\(_3\)H\(^{+}\) [M + H\(^+\)]\(^1\) 306.2103, found 306.2110.

\((2S,3R)-3\text{-Fmoc-amino-2-methylhexanoic acid} \text{-14})\. TFA (5.0 mL) was added to a solution of \(\beta\)-amino ester 13 (224 mg, 0.73 mmol) in anhydrous CH\(_2\)Cl\(_2\) (5.0 mL). After 25 hours the reaction mixture was concentrated and residual TFA was removed by co-evaporation with toluene (3 × 10 mL). The resulting residue was dissolved in dioxane (5.0 mL) and HCl in dioxane (4 M, 0.55 mL, 2.2 mmol, 3.0 equiv.) was added. After 1.5 hours the mixture was concentrated. The crude fully deprotected \(\beta\)-amino acid was suspended in water (5.0 mL) at 0 °C and Na\(_2\)CO\(_3\) (311 mg, 2.93 mmol, 4.0 equiv.) was added followed by Fmoc-O-succinimide (297 mg, 0.88 mmol, 1.2 equiv.) in DMF (3.0 mL). Cooling was removed and DMF (2.0 mL) was added. After 1.5 hours, water (5.0 mL) was added and after additionally 1.5 hours of stirring the reaction mixture was diluted with water (60 mL) and extracted with Et\(_2\)O (15 mL). After acidification with concentrated HCl, until pH ≈ 1–2, the aqueous layer was extracted with EtOAc (3 × 75 mL). The combined organic phases were dried (MgSO\(_4\)), filtered, and concentrated in vacuo. Purification of the crude residue by vacuum silica gel chromatography afforded \(\beta\)-amino acid 14 (66 mg, 25%, 3 steps) as a white solid after co-evaporation of residual acetic acid with CH\(_2\)Cl\(_2\)–toluene (1 : 1, 3 × 10 mL); \(^1\)H NMR (300 MHz, DMSO-d\(_6\)) \(\delta\) 12.19 (s, 1H), 7.86 (d, \(J = 7.4\) Hz, 2H), 7.66 (dd, \(J = 7.3, 2.9\) Hz, 2H), 7.38 (t, \(J = 7.4\) Hz, 2H), 7.30 (d, \(J = 7.4\) Hz, 2H), 7.05 (d, \(J = 9.5\) Hz, 1H), 4.31 (m, 2H), 4.18 (t, \(J = 6.7\) Hz, 1H), 3.58 (m, 1H),
ether afforded the TFA salt of the linear peptide 16 (53 mg, 81% from 2-chlorotriyl chloride resin, based on theoretical loading of resin) as a white solid. UPLC-MS, \( t_{\text{R}} = 0.84 \) min, calcd for \( \text{C}_{24}\text{H}_{36}\text{N}_{4}\text{O}_{5}\text{H}^{+} \left[ \text{M} + \text{H} \right]^{+} \) 479.3, found 479.3; \( ^1\text{H} \) NMR (400 MHz, MeOD) \( \delta \) 7.04 (d, \( J = 8.2 \) Hz, 2H), 6.69 (d, \( J = 8.2 \) Hz, 2H), 4.58 (m, 1H), 4.38 (m, 1H), 4.15 (d, \( J = 7.1 \) Hz, 1H), 3.38 (m, 1H), 3.07 (dd, \( J = 14.0, 5.3 \) Hz, 1H), 2.92 (dd, \( J = 14.0, 7.8 \) Hz, 1H), 2.79 (m, 1H), 2.05 (octet, \( J = 6.9 \) Hz, 1H), 1.60 (q, \( J = 7.8 \) Hz, 2H), 1.54–1.39 (m, 2H), 1.33 (d, \( J = 7.1 \) Hz, 3H), 1.21 (d, \( J = 7.2 \) Hz, 3H), 0.93 (t, \( J = 7.3 \) Hz, 3H), 0.93 (d, \( J = 6.8 \) Hz, 6H).

**Cyclic peptide 9.** Linear peptide 16 (50 mg, 0.084 mmol) was dissolved in DMF (200 mL = 0.4 mM) and iPr$_2$NET (73 \( \mu \)L, 0.42 mmol, 5.0 equiv.) and HATU (48 mg, 0.13 mmol, 1.5 equiv.) were added. After stirring for 19 hours the reaction mixture was concentrated in vacuo. The residue was taken up in CH$_2$Cl$_2$ (80 mL) and washed with aqueous HCl (1 M, 25 mL) and the aqueous phase was re-extracted with CH$_2$Cl$_2$ (50 mL). The combined organics were washed with brine (25 mL) dried (MgSO$_4$), filtered, and concentrated in vacuo. The resulting residue was dissolved in DMF (2.5 mL) and purified by preparative HPLC on a [250 mm × 20 mm, C$_{18}$ Phenomenex Luna column (5 \( \mu \)m, 100 Å)] using an Agilent 1260 LC system to afford the cyclic peptide 9 (2.7 mg, 7%) as a white solid. A gradient with eluent III (95 : 5 : 0.1, water-MeCN-TFA) and eluent IV (0.1% TFA in acetonitrile) rising linearly from 0% to 95% of eluent IV during \( t = 5-45 \) min was applied at a flow rate of 20 mL min$^{-1}$. Two conformations are observed in the $^1$H NMR spectrum. The conformations are present in an 88 : 12 ratio. Characterization is given for the major conformation. $^1$H NMR (500 MHz, DMSO-d$_6$) \( \delta \) 8.91 (br s, 1H), 7.67 (d, \( J = 8.8 \) Hz, 1H), 7.55 (d, \( J = 9.0 \) Hz, 1H), 7.46 (d, \( J = 8.4 \) Hz, 1H), 6.96 (m, 3H), 6.63 (d, \( J = 8.4 \) Hz, 2H), 4.14 (p, \( J = 7.3 \) Hz, 1H), 4.07 (p, \( J = 8.8 \) Hz, 1H), 3.99 (m, 1H), 3.67 (d, \( J = 9.4 \) Hz 1H), 2.89 (dd, \( J = 13.7, 7.2 \) Hz, 1H), 2.81 (dd, \( J = 13.7, 9.0 \) Hz, 1H), 2.54 (m, 1H), 2.16 (m, 1H), 1.64 (m, 1H), 1.36 (m, 1H), 1.25–1.15 (m, 8H), 0.91–0.77 (m, 9H); HRMS (ESI-TOF) calcd for C$_{23}$H$_{29}$N$_{4}$O$_{4}$H$^{+} \left[ \text{C}_{44}\text{H}_{36}\text{N}_{4}\text{O}_{5}\text{H}^{+} \right]^{+}$ 461.2719, found 461.2754; HPLC gradient B, \( t_{\text{R}} = 11.14 \) min (>93%).

**Biochemical profiling.**

*In vitro histone deacetylase inhibition assays.* For assaying, peptides were reconstituted in DMSO to give 5–10 mM stock solutions, the accurate concentrations of which were determined by UV using the extinction coefficient for tyrosine at 280 nm; \( \varepsilon = 1280 \) M$^{-1} \times $cm$^{-1}$. Inhibition of recombinant human HDACs in dose–response experiments with internal controls was measured in black low binding Corning half-area 96-well microtiter plates. The appropriate dilution of inhibitor (5 \( \mu \)L of 5× the desired final concentration, prepared from 5–10 mM DMSO stock solutions) was added to each well followed by substrate in HDAC assay buffer (10 \( \mu \)L). Ac–Leu–Gly–Lys (Ac)–AMC was used at a final concentration of 20 \( \mu \)M for HDAC1, 2, 3, 6, and 11. Ac–Leu–Gly–Lys (Tfa)–AMC was used at a final concentration of 20 \( \mu \)M for HDAC4, 120 \( \mu \)M for HDAC5, 40 \( \mu \)M for HDAC7 and 200 \( \mu \)M for HDAC8, and 80 \( \mu \)M for HDAC9. Ac–Arg–His–Lys (Ac)–Lys (Ac)–AMC was used at a final...
concentration of 5 μM for HDAC10. Finally, a freshly prepared solution of the appropriate HDAC (10 μL) was added and the plate (containing a final volume of 25 μL in each well) was incubated at 37 °C for 30 min. The final concentrations of enzyme was as follows: HDAC1: 1 ng μL⁻¹, HDAC2: 0.5 ng μL⁻¹, HDAC3-NCoR2: 0.09 ng μL⁻¹, HDAC4: 0.04 ng μL⁻¹, HDAC5: 0.2 ng μL⁻¹, HDAC6: 2.4 ng μL⁻¹, HDAC7: 0.04 ng μL⁻¹, HDAC8: 0.2 ng μL⁻¹, HDAC9: 0.8 ng μL⁻¹, HDAC10: 4 ng μL⁻¹, HDAC11: 10 ng μL⁻¹. Then trypsin (25 μL, 0.4 mg mL⁻¹) was added and the assay development was allowed to proceed for 15–30 min at room temperature, before the plate was read using a Perkin Elmer Enspire plate reader with excitation at 360 nm and detecting emission at 460 nm. Each assay was performed in duplicate and repeated at least twice. The data were analyzed by non-linear regression using GraphPad Prism to afford IC₅₀ values from the dose–response experiments, and Kᵢ values were determined from the Cheng–Prusoff equation, Kᵢ = IC₅₀/(1 + [S]/Kₑₙ), assuming a standard fast-on–fast-off mechanism of inhibition. The applied Kₑₙ values were previously reported for HDACs 1–3, HDAC8, and HDAC11.²⁶

Continuous assay protocol. The continuous assays of HDAC3-NCoR2 inhibition were performed in 96-well, white, medium binding, half-area microtiter plates (Greiner Bio One). The 2- or 3-fold dilution series of inhibitors were prepared as described above. HDAC assay buffer (10 μL) containing substrate Ac–Leu–Gly–Lys (Ac–AMC) (100 μM; final concentration 20 μM) and HDAC assay buffer (10 μL) containing trypsin (12.5 ng μL⁻¹; final concentration 2.5 ng μL⁻¹) was added to each well, followed by the appropriate dilution of inhibitor (20 μL of 2.5× the desired final concentration). Finally, a solution of HDAC3-NCoR2 (10 μL, 0.2 ng μL⁻¹ = 2.5 nM; final concentration 0.04 ng μL⁻¹ = 0.5 nM) was added, and fluorescence readings were recorded every 30 seconds for 45 min at 25 °C using a Perkin Elmer Enspire plate reader with excitation at 360 nm and detecting emission at 460 nm. Each assay was performed twice in duplicate. The rate constants (ν) were determined by linear regression analysis using GraphPad Prism. Kᵢ values were then determined by non-linear fitting to the following equation, νᵢ/ν₀ = (1 + [I]/[Kᵢ(1 + [S]/Kₑₙ)])⁻¹.²

In vitro cell proliferation assay. Cell proliferation was assessed using the MTT cell growth kit (Millipore, Billerica, MA, USA). EB-3 cells (ATCC, Manassas, VA, USA) were seeded in 96-well flat-bottom cell culture plates (Nunc, Thermo Fischer Scientific, Roskilde, Denmark) with a density of 2 × 10⁴ cells in 90 μL culture media composed of RPMI-1640 (ATCC, Manassas, VA, USA) supplemented with 10% fetal calf serum (FCS) (Sera Scandia, Hellerup, Denmark) and 1% penicillin/streptomycin (Gibco, Invitrogen, Taastrop, Denmark). After cultivation overnight at 37 °C in humid 5% CO₂ atmosphere, 10 μL of culture medium containing appropriate concentrations of the five compounds or the vehicle (DMSO) as control were added. The 2-fold dilution series were prepared from DMSO stock solutions (5 mM for azumamide C and 10 mM for the remaining compounds) to give final assay concentrations starting from 50 μM for azumamide C, SAHA, and apicidin while 100 μM was applied for azumamide B and compound 9. After incubation for 3 days, MTT solution was freshly prepared by dissolving 3-(4,5-dimethylthiazol-2-yl)-2,5-

diphenyltetrazolium bromide (MTT, 50 mg) in PBS (10 mL, both supplied in the MTT assay kit) and 10 μL of this solution was added to each well. The cells were incubated for another 4 h at 37 °C in humid 5% CO₂ atmosphere for development to take place. The purple formazan crystals produced were dissolved by addition of isopropanol alcohol (100 μL per well) containing HCl (0.04 M), and the absorbance was measured at 570 nm with background subtraction at 630 nm on a Tecan Sunrise ELISA plate reader (Tecan, Switzerland). All assays were performed three times in duplicate.

**General Experimental**

**Materials and methods.** All chemicals and solvents were analytical grade and used without further purification. Vacuum liquid chromatography (VLC) was performed on silica gel 60 (particle size 0.015–0.040 µm). UPLC–MS analyses were performed on a Waters Acquity ultra high-performance liquid chromatography system. A gradient with eluent I (0.1% HCOOH in water) and eluent II (0.1% HCOOH in acetonitrile) rising linearly from 0% to 95% of II during t = 0.00–2.50 min was applied at a flow rate of 1 mL/min. Analytical HPLC was performed on a [150 mm × 4.6 mm, C\textsubscript{18} Phenomenex Luna column (3 µm)] using an Agilent 1100 LC system equipped with a UV detector. A gradient, B, with eluent III (95:5:0.1, water–MeCN–TFA) and eluent IV (0.1% TFA in acetonitrile) rising linearly from 0% to 95% of IV during t = 2–20 min was applied at a flow rate of 1 mL/min. Preparative reversed-phase HPLC was performed on a [250 mm × 20 mm, C\textsubscript{18} Phenomenex Luna column (5 µm, 100 Å)] using an Agilent 1260 LC system equipped with a diode array UV detector and an evaporative light scattering detector (ELSD). A gradient C with eluent III (95:5:0.1, water–MeCN–TFA) and eluent IV (0.1% TFA in acetonitrile) rising linearly from 0% to 95% of IV during t = 5–45 min was applied at a flow rate of 20 mL/min. 1D and 2D NMR spectra were recorded on a Varian INOVA 500 MHz instrument, a Bruker Ascend 400 MHz or a Varian Mercury 300 instrument. All spectra were recorded at 298 K. For the Varian INOVA 500 MHz instrument and the Varian Mercury 300 instrument 1D NMR spectra were recorded at 499.9 MHz and 300 MHz for 1H and 100 MHz and 75 MHz for 13C, respectively. The correlation spectroscopy (COSY) spectra were recorded with a relaxation delay of 1.5 sec before each scan, a spectral width of 6k × 6k, collecting 8 FIDs and 1k × 512 data points. Heteronuclear single quantum coherence (HSQC) spectra were recorded with a relaxation delay of 1.5 sec before each scan, a spectral width of 6k × 25k, collecting 16 FIDs and 1k × 128 data points. Heteronuclear 2-bond correlation (H2BC) spectra were recorded with a relaxation delay of 1.5 sec before each scan, a spectral width of 4k × 35k, collecting 16 FIDs at 295 K and 1k × 256 datapoints. Heteronuclear multiple-bond correlation (HMBC) spectra were recorded with a relaxation delay of 1.5 sec before each scan, a spectral width of 6k × 35 k, collecting 32 FIDs and 1k × 256 datapoints. Finally, on the Bruker Ascend 400 MHz the 1D NMR spectra were recorded at 400 MHz for 1H and 100 MHz for 13C. The correlation spectroscopy (COSY) spectra were recorded with a relaxation delay of 1.5 sec before each scan, a spectral width of 3k × 3k, collecting 4 FIDs and 1k × 128 data points. The heteronuclear single quantum coherence (HSQC) spectra were recorded with a relaxation delay of 1.5 sec before each scan, a spectral width of 4800 × 16600, collecting 4 FIDs and 1k × 256 datapoints. Chemical shifts are reported in ppm relative to deuterated solvent peaks as internal standards (δH, DMSO-\textsubscript{d6} 2.50 ppm; δC, DMSO-\textsubscript{d6} 39.52 ppm, δH, CDCl\textsubscript{3} 7.26 ppm; δC, CDCl\textsubscript{3} 77.16 ppm). Coupling constants (J) are given in hertz (Hz). Multiplicities of \textsuperscript{1}H NMR signals are reported as follows: s, singlet; d, doublet; t, triplet; q, quartet; m, multiplet.
**Assay materials.** HDAC1 (Purity ≥62% by SDS-PAGE according to the supplier), HDAC2 (Full length, purity ≥94% by SDS-PAGE according to the supplier), HDAC3-NCoR2 complex (Purity ≥80% by SDS-PAGE according to supplier) and HDAC 5 (Full length, purity ≥90% by SDS-PAGE according to the supplier), HDAC8 (Purity ≥90% by SDS-PAGE according to the supplier), HDAC9 (Full length, purity ≥76% by SDS-PAGE according to the supplier) and HDAC10 (Purity ≥1% by SDS-PAGE according to the supplier) were purchased from BPS Bioscience (San Diego, CA 92121). HDAC 7 (Purity ≥90% by SDS-PAGE according to the supplier) was purchased from Millipore (Temecula, CA 92590). HDAC6 (Purity ≥85% by SDS-PAGE according to the supplier) and HDAC11 (Purity ≥50% by SDS-PAGE according to the supplier) were purchased from Enzo Life Sciences (Postfach, Switzerland). The HDAC assay buffer (50 mM tris/Cl, pH 8.0, 137 mM NaCl, 2.7 mM KCl, 1 mM MgCl₂) was added bovine serum albumin (0.5 mg/mL). Trypsin (10,000 units/mg, TPCK treated from bovine pancreas) was from Sigma Aldrich (Steinheim, Germany). All peptides were purified to homogeneity (>95% purity by HPLC using reversed-phase preparative HPLC), and the white fluffy materials obtained by lyophilization were kept at –20 °C.

**Figure S1.** Single-dose HDAC inhibition experiments.\(^a\)

\(^a\)With SAHA (vorinostat) as control compound, we tested the ability of compound 9 as well as the shown linear azumamide C analogue (C) to inhibit all the zinc-dependent recombinant human HDAC enzymes at 10 µM (A) and 100 µM concentrations (B), respectively. *HDAC3 was applied as a complex with NCoR2.

\end{figure}

\textsuperscript{a}With SAHA (vorinostat) as internal control compound in all assay plates, we performed dose-response experiments in at least two individual assays performed in duplicate. Data for Azumamide B are taken from a previous publication (ref 29, J. S. Villadsen, H. M. Stephansen, A. R. Maolanon, P. Harris, and C. A. Olsen, \textit{J. Med. Chem.}, 2013, \textbf{56}, 6512-6520) Data were analyzed and plotted using the GraphPad Prism software. *HDAC3 was applied as a complex with NCoR2.
