**Introduction and objectives**

It is challenging to control and express exposure of hydrophobic organic compounds in aquatic toxicity experiments, due to the sorption of these compounds to vessel surfaces and organic material. In the current study, passive dosing was used to tightly control exposure throughout toxicity experiments [1], while chemical activity was used to express exposure and form basis for comparison of toxicity data [2].

This study addresses the acute toxicity of pyrethroid insecticides towards the aquatic invertebrate *Daphnia magna* and asks:

1. Is pyrethroid toxicity generally underestimated in the literature due to poorly controlled exposure?
2. At which chemical activity do pyrethroids exert their toxicity, and how similar are the median effect chemical activity (EC₅₀) for different pyrethroids?
3. How much more toxic are pyrethroids relative to baseline toxicity?

**Results**

**Figure 2.** Immobilisation (%) of *Daphnia magna* after 48 h exposure to the three pyrethroids as a function of freely dissolved concentration (C_freetoxicant). The median effect concentrations (EC₅₀) are given, with ranges of literature EC₅₀ values indicated by dark grey beams. The EC₅₀ values correspond to 160 pmol L⁻¹ (95% CI: 149-219 pmol L⁻¹) for cypermethrin, 333 pmol L⁻¹ (95% CI: 298-374 pmol L⁻¹) for esfenvalerate and 357 pmol L⁻¹ (95% CI: 300-426 pmol L⁻¹) for bifenthrin. Error bars represent the standard error of the mean (n=6).

**Figure 3.** Regression of subcooled liquid solubility (S_L, mmol L⁻¹; solid line [13] and lines representing the chemical activity 0.1, 0.01, 0.001 and 0.0001 (a, unit less, broken line). The lines are the chemical activity range of (10⁻¹⁰⁻¹) for the initiation of baseline toxicity, EC₅₀ values of naphthalene (1), phenanthrene (2), α-cypermethrin (3), esfenvalerate (4) and bifenthrin (5) are plotted against their S_L values. The median effect chemical activity (EC₅₀) is +0.000032, ±0.00033 and +0.00079 for α-cypermethrin, esfenvalerate and bifenthrin, respectively.

**Conclusions**

Based on current data, the following was concluded:

1. In general, the median effect concentrations (EC₅₀) were in agreement with lowest literature values (Figure 2), and these studies thereby validate each other. To the contrary, higher literature values seem to underestimate pyrethroid toxicity.

2. The three pyrethroids had median effect chemical activities (EC₅₀) in the chemical activity range 0.00001 to 0.001 (Figure 3), corresponding to median immobilisation at 0.01 to 1% of the pyrethroid’s subcooled liquid solubility. The EC₅₀ values were within 2 orders of magnitude.

3. The three pyrethroids were 1-3 orders of magnitude more toxic relative to baseline toxicity (Figure 3). In this way, excess toxicity was expressed by EC₅₀ values well below the chemical activity range 0.01 to 0.1 for the initiation of baseline toxicity.

**Experimental**

Passive dosing with silicone was used to set and maintain freely dissolved concentrations of α-cypermethrin, esfenvalerate and bifenthrin in 48-h immobilisation experiments with *Daphnia magna*.

- Silicone elastomer was cast in glass vials.
- Silicone was loaded with test compounds (C_silicone).
- Test organisms were exposed in water, continuously equilibrated with loaded silicone (C_freetoxicant).
- Exponents to determine partition ratios (K_freetoxicantwater) for the specific silicone are ongoing.

**Acknowledgements and References**

We thank Anja Weibell and Margit M. Fernqvist for guidance and assistance with *Daphnia magna* and passive dosing, respectively. We also thank Nania Mejías, Maj-Britt A. Bjejager and Emilie Reiler for help during the toxicity experiments. The research was financially supported by the European Commission (OSIRIS, COOE 037017) and UUver UK Central Resources Limited (Contact CH-2013-0093).
