**Introduction**

When a signal varies in its properties along the time and frequency, this is considered a modulation. Speech signals exhibit temporal and spectral modulations. The sensitivity to these modulations has been studied in normal-hearing (NH) listeners, yielding temporal, spectral, and spectro-temporal modulation transfer functions (Dau et al. 1997, Edin & Bero 2007, Chi et al. 1999). Recently, Mehraei et al. (2014) showed significant differences between normal-hearing and hearing-impaired (HI) listeners in spectro-temporal modulation detection and also the relation between STM sensitivity to speech intelligibility in noise. Moreover, Henry et al. (2005) showed large differences in STM discrimination tasks. The present study attempted to establish the limits of STM perception in NH listeners and two groups of HI (with either good or poor speech intelligibility).

**Motivation**

The reduced STM sensitivity in HI listeners has been ascribed to temporal fine structure processing deficits and a loss of frequency selectivity (Bernstein et al., 2013, Mehraei et al. 2014). The main assumption of this study is that the individual differences in STM sensitivity can be related to the existence of supra-threshold distortions (Plomp, 1986).

**Research Questions**

Q1: Where are the limits of STM perception in NH listeners for narrow-band noise carriers?

Q2: Can supra-threshold distortions be characterized by STM detection thresholds?

**Experiment I: Limitations in STM sensitivity and discrimination in NH listeners**

**Method**

Subjects: 15 Young NH listeners

Procedure: 3 AFC, 1 up 2 down

Stimuli: Level: 35 dB SL

Modulated 1 octave bands

- f = 1 kHz, f0 = 4 kHz
- f = 4 kHz, f0 = 4 kHz

- Level: STMD and TMD

- 3 IF, 1 up 3-down procedure

TM detection:

- Same frequencies (1 and 4 kHz) and f0 (4 kHz)

**Results**

Fig. 2: A) Detection thresholds for temporal (TMD), spectral (SMD) and spectro-temporal modulations (STMD).

- The STMD thresholds were lower (better) than only TMD

B) Spectro-temporal ripple discrimination (STRD) and Spectral (SRD) ripple discrimination for 1-octave band modulated noises.

- There was no significant difference for the frequency conditions.

- STRD threshold was lower and was found less suitable for a clinical set-up.

**Experiment II: Spectro-temporal modulation sensitivity and hearing deficits**

**Method**

Subjects: 23 subjects were divided in three groups by means of the SISI® questionnaire for Speech:

- 5 NH, 9 HIa, 9 HIb

STM detection:

- 2 conditions:

  - 1 kHz, f0 = 4 Hz
  - 4 kHz, f0 = 4 Hz

- Level: STMD and TMD

- 3 IF, 1 up 3-down procedure

TM detection:

- Same frequencies (1 and 4 kHz) and f0 (4 kHz)

**Results**

Fig. 3: STM sensitivity individual results (ears) for the NH, HIa, and HIb groups. Results at 0 dB show the subjects which were not able to perform the test.

- In condition at 4 kHz, HI presented reduced STM thresholds. HIb showed a difference with NH of 9 dB and HIa of 12.

- There was a significant difference between the two HI groups (p<0.05) at 4 kHz but not at 1 kHz.

- Some of the subjects were not able to detect the STM in both conditions.

**Conclusion and Outlook**

In the present study the HI listeners were divided in two groups by means of the SISI® questionnaire. Significant differences were observed between the two groups in STMD. Overall, these results suggested that the two groups may be affected by different impairments. Within the Better HiAring Rehabilitation (BEAR) project, a new battery test will provide information about the hearing deficits beyond the audiogram. The results from the present study suggests that spectro-temporal modulation detection might be a good candidate for characterizing hearing deficits towards a clinical profiling.
