1. Introduction

Chinese High-speed Railway

- **Construction of high-speed railway network**
  - By September of 2016 the HSR network was already approximately 22,000 km in length, accounted for more than 60% of the world’s high speed rail track.
  - Plans to increase this further to 30,000 km by 2020 and to 38,000 km by 2025.

- **Rolling stock**
  - The HSR has a fleet of 2,600 trains. On any given day approximately 2,300 of these are in operation and collectively cover around 4,500 timetabled services.
  - All rolling stock units must be regularly maintained to ensure the safety of the system.
  - 24 depots are scattered throughout the HSR network.
1. Introduction

Rolling stock schedule

- The timetable for the HSR is revised annually (however, there may also be slight adjustments during peak periods and holidays, e.g., Chinese New Year).
- Usually, when the timetable requires modification, all dispatchers meet to devise a new rolling stock schedule.

Problem

As the rolling stock planning is mainly a manual process in China, it is often difficult to quickly obtain an optimal rolling stock schedule that covers the timetable and which also adheres to the rolling stock maintenance requirements.
2. Problem descriptions

The rolling stock scheduling problem involves assigning so-called *compositions* to a set of timetabled services.

- Rolling stock unit: 8 cars
- (de) coupling can take place at depot and stations (with depot track)

![Figure 1 Examples of train compositions](image)
2. Problem descriptions

The services specified in the timetable are defined by a set of *trips*. Each *trip* specifies the movement of a train between two stations at a specific time. And also a minimal number of units required on each trip is forecasted.

Type AL and B are used to serve these trips.

Figure 4 Schedule 2
2. Problem descriptions

When considering maintenance, a trip sequence can only be assigned to a unit if the time and mileage consumption of the trip sequence is less than the remaining time and mileage of the unit in question.

We focus on level one maintenance (or daily maintenance). This stipulates that all rolling stock units undergo a maintenance check every two days, or when the accumulated mileage exceeds 5,500km.

The rolling stock scheduling problem that we consider therefore involves not only determining the best composition for each trip, but also deciding how to assign compositions in such a way that the trip sequences assigned to each individual unit do not violate the maintenance requirements specified.
3. Two-stage approach

Decompose the problem into two stages:

- a conventional flow based model: ignoring maintenance, to obtain multiple rolling stock schedules.
- a series of assignment problems: considering maintenance, using the solutions found in the first stage.

**Assumptions:**

- The timetable is known before scheduling any rolling stock units.
- Not all stations can be used for overnight parking.
- Dead heading units to start trips is possible.
- All rolling stock units must go through a coupling and a decoupling procedure at the start and end of every trip sequence.
3. Two-stage approach

Approach:

- Arc-Flow model
- Obtain best 50 solutions (solution pool)
- Generate all the possible path for each solution
- Assign model 1, Assign model 2, ..., Assign model 49, Assign model 50
- If no feasible solution, go back to the pool
- Optimal solutions (some may be infeasible)
- Choose the solution with minimal objective value (arc-flow model plus assign model)

Figure 5 Flow diagram for the proposed approach
3. Two-stage approach

**Arc-flow model:** (Haahr, Nielsen)

**Objective:**

\[
\min z = \sum_{t \in T} \sum_{c \in C} \text{operCost}^t_c \cdot y^t_c + \sum_{r \in C} \sum_{c \in C} \sum_{c' \in C} \text{changeCost}^r_{c,c'} \cdot X^r_{c,c'} + \sum_{p \in P} \sum_{d \in D} \text{penEod} \cdot i^p_d + \text{emptyMileage} + \text{overTime}
\]

**Subject to:**

(1) Trip Uniqueness

\[
\sum_{c \in C} y^t_c + \sum_{c \in C} y^{t'}_c = 1 \quad \forall t \in \text{one}T, t' \in \text{two}T
\]

\[
\sum_{c \in C} y^t_c \leq 1 \quad \forall t \in \text{empty}T : A_t, B_t \notin D
\]
3. Two-stage approach

Arc-flow model:

Subject to:

(2) Flow Feasibility

\[
\sum_{r \in \text{Cnn}} \sum_{(c,c') \in C^r_{c,c'}} X_{c,c'}^r = y_t^c \quad \forall t \in T : A_t, B_t \notin D, c \in C
\]

\[
\sum_{r \in \text{Cnn}} \sum_{(c,c') \in C^r_{c',c}} X_{c',c}^r = y_t^c \quad \forall t \in T : A_t, B_t \notin D, c \in C
\]

(3) Depot Inventory

In order to precisely monitor the inventory levels, the number of rolling stock units of type $p \in P$ that are (de)coupled to the composition at connection $r \in \text{Cnn}$ must be determined.

\[
v1_r^p = \sum_{c \in C} \sum_{(c,c') \in C^r_{c,c'}} X_{c,c'}^r \cdot \text{couple}_{c,c'}^p \quad \forall r \in \text{Cnn}, p \in P
\]

\[
v2_r^p = \sum_{c \in C} \sum_{(c,c') \in C^r_{c,c'}} X_{c,c'}^r \cdot \text{decouple}_{c,c'}^p \quad \forall r \in \text{Cnn}, p \in P
\]
3. Two-stage approach

Arc-flow model:

Subject to:

(3) Depot Inventory

\[
storage_{p,d}^{\text{time}} = bod_d^p - \sum_{\substack{r \in \text{Cnn:} \\ B_r = d, \\ t\text{Coupling}_r \leq \text{time}}} v1_r^p + \sum_{\substack{r \in \text{Cnn:} \\ A_r = d, \\ t\text{Decoupling}_r \leq \text{time}}} v2_r^p \\
+ \sum_{\substack{r \in \text{Cnn:} \\ s_r, t_r \in \text{meT}, \\ t\text{Decoupling}_r \leq \text{time}}} g_r^d - \sum_{\substack{r \in \text{Cnn:} \\ s_r, t_r \in \text{meT}, \\ t\text{Coupling}_r \leq \text{time}}} h_r^d \quad \forall \text{time} \in \text{Time}, p \in P, d \in D
\]

Note: here the used rolling stock units are divided into two parts: units that are (de)coupled at the depot and those that are (de) coupled at stations. which are not necessary for the model, but help us to identify the corresponding depot of (de) coupled units.
3. Two-stage approach

Arc-flow model:

Subject to:

(4) Depot Inventory-additional

\[
\sum_{d \in D} g_{r,p}^d = v2^p_r \quad \forall r \in Cnn : s_r, t_r \in meT; p \in P
\]

\[
\sum_{d \in D} h_{r,p}^d = v1^p_r \quad \forall r \in Cnn : s_r, t_r \in meT; p \in P
\]

\[
\sum_{d \in D} h_{r,p}^d \leq 1 \quad \forall r \in Cnn : s_r, t_r \in meT; p \in P
\]

\[
\sum_{d \in D} g_{r,p}^d \leq 1 \quad \forall r \in Cnn : s_r, t_r \in meT; p \in P
\]
3. Two-stage approach

**Trip Sequence Assignment MIP:**

**Objective:**

\[
\min z = \sum_{i \in L} \sum_{\text{roll} \in \text{Rolling}} j^l_{\text{roll}} \cdot \text{assCost}_{\text{roll}}
\]

**Subject to:**

There are two main types of constraints in the MIP model. The first ensures that the number of rolling stock units assigned to each trip is consistent with the solution to the arc flow formulation. The second ensures that each unit receives at most one trip sequence.

\[
\sum_{\text{roll} \in \text{Rolling}} \sum_{l \in \text{Lroll}} a^t\cdot j^l_{\text{roll}} = b_t \quad \forall t \in \text{meT}
\]

\[
\sum_{l \in \text{Lroll}} j^l_{\text{roll}} \leq 1 \quad \forall \text{roll} \in \text{Rolling}
\]
3. Two-stage approach

**Algorithm:**

Step 1: Using the results of the arc-flow model, identify all unit flows (from depot to depot). Divide the flows into two sets: one set contains flow without composition changes outside the depot, while the other contains composition changes outside of the depot.

Step 2: For the flows without composition changes outside the depot, split each flow into individual trip sequences.

![Illustration of flow without composition change](image)

Figure 6 Illustration of flow without composition change
3. Two-stage approach

Algorithm:

Step 3: split the flows with composition changes outside the depot

Figure 7 Illustration of flow with composition change
3. Two-stage approach

**Algorithm:**

Step 4: After steps 2 and 3, all the flow is represented as partial trip sequences for a single rolling stock unit. Based on the partial trip sequences, it is easy to enumerate all full trip sequences.
4. Results

Setting:

- A real-life instance provided by the Chinese High Speed Railway (Zhengzhou railway).
- 31 main stations and two depots.
- Three different rolling stock types: 5 composition changes.
- A total of 91 units and 377 trips.

Figure 8 Sketch of China Zhengzhou Railway
4. Results

Setting:

<td>-38.5%</td>
<td>-31.3%</td>
<td>-</td>
<td>-6.1%</td>
</tr>
</tbody>
</table>

- the proposed optimization method can significantly reduce the deadhead mileage: The total deadhead mileage is reduced by 2039 km (38.5%)
- the average rolling stock mileage has increased by 243.4 km (10%)

A reduction in dead head mileage and an increase rolling stock mileage both help improve the efficiency of the rolling stock schedule.

- the 6% reduction in operating cost: Maintaining and operating a HSR is not cheap, and a 6% reduction in operating costs results in substantial savings.
4. Results

Manual schedule and computational schedule (with maintenance):

The main reasons for the improvements can be seen in Table 7 and Table 8

| Table 7: Technical statistics of dispatcher schedule and computational schedule |
|-----------------------------|---------------|-----------------|------------------|
|                            | Coupling times | Decoupling times | Rolling stock swaps |
| Algorithm                  | 2             | 3               | 10               |
| Dispatcher                 | -             | -               | -                |

| Table 8: Basic information of used rolling stock units |
|-----------------------------------------|---------------|---------------|-----------------|
| Depot         | CRH380AL | CRH380A | CRH380B | Utilization |
| Maintenance   |          |          |          |             |
| Zhengzhou     | 0        | 0        | 11      | 61.1%       |
| Zhengzhoudong | 16       | 0        | 24      | 54.8%       |
| Dispatcher     |          |          |          |             |
| Zhengzhou     | 0        | 5        | 5       | 55.6%       |
| Zhengzhoudong | 22       | 4        | 21      | 64.4%       |

- Manual schedule: no composition changes at all
- Computational schedule provides an additional level of flexibility
- The rolling stock units with lowest operation cost are considered first in computational schedule
5. Conclusion

Contributions:

- Present a two stage approach for solving the rolling stock scheduling problem with maintenance.
- A real-world instance provided by the Zhengzhou HSR network has been used to test the performance of the propose approach. Also the results is verified by dispatchers.

Future study:

- Different timetable for special occasions.
- Compare with other algorithms.
- Impact of the new depot location.
Thank you for your attention!
