Citation (APA):
We present the development of a detection strategy based on surface-enhanced Raman spectroscopy (SERS) sensing in water. The SERS substrates, fabricated from free-standing, gold-capped silicon nanopillars are commonly used for the detection of analytes dissolved in organic solvents and dried on the sensor surface. We developed a method where detection can be performed directly in aqueous samples using a model drug acetaminophene (Paracetamol).

**SERS Substrate - Gold Capped Nanopillars**

SERS is a powerful analysis technique capable of detecting molecular fingerprints of analytes with high sensitivity and fast response time. [2]

Classical dry droplet SERS sensing using gold-capped Si nanopillars. [3] Dry droplet measurements are highly influenced by the chosen sample matrix. Complex matrices can lead to sensor fouling. Organic solvents are preferred, due to the hydrophobic nature of the nanopillar surface.

Dry droplet SERS-based detection of 350 µM paracetamol in various aqueous matrices.

**Surface Treatment**

UV/ozone exposure is commonly utilized as surface treatment and cleaning procedure in a variety of microfabrication processes. It renders the surface of gold-capped nanopillars from hydrophobic to hydrophilic without any morphological alterations.

Direct Paracetamol detection in MQ was possible over a linear range of 5 – 100 µM. 350 µM Paracetamol spiked in PBS, tap water and unfiltered river water shows that UV/Ozone pre-treatment allows detection in a realistic environment.

**UV/ Ozone Treatment**

UV/ozone surface treatment resulted in a lowered background signal, more defined peak shape and homogenous wettability in aqueous samples in comparison to untreated and pre-cleaned samples. Optimal signals were obtained after 30 min of treatment and samples were stable for 3 hrs in an ambient environment.

Liquid Measurements

UV/ozone treatment enabled the development of a novel liquid measurement technique for nanopillar SERS based sensing.
