ABSTRACT

NO\textsubscript{X} emission from fluidized bed combustion is primarily determined by a series of competing formation and reduction reactions from fuel bound nitrogen. To provide an improved understanding of NO\textsubscript{X} emission from fluidized bed combustion of biomass, a systematic evaluation of the impact of fuel properties, including nitrogen content, mineral content, and co-combustion, on NO\textsubscript{X} emission was investigated.

Continuous biomass combustion experiments were conducted in a lab-scale fluidized bed reactor. At otherwise similar conditions, a variety of biomass fuels, including pine wood, beech wood, straw, sunflower husk, sunflower seed, and sewage sludge, were combusted with the emission of NO\textsubscript{X} monitored. The impact of co-combustion of selected fuels was examined at air staged and one-stage conditions. In addition, the interaction between ash forming elements and NO\textsubscript{X} emission was investigated by combustion of washed and K-doped (KCl, K\textsubscript{2}CO\textsubscript{3}, and KOH) biomass.

Selected results from the experiments are shown in Figure 1 and 2. The results in Figure 1 indicate that the NO emissions from straw-sunflower seed and straw-sunflower husk co-combustion were additive, while a synergy effect was observed in the case of sewage sludge-straw co-combustion. This may be attributed to the catalytic effect of sewage sludge ash on the nitrogen chemistry. The results in Figure 2 show that the conversion of fuel nitrogen to NO decreased with the fuel nitrogen content, increased when washing the straw, and decreased slightly upon K-doping of the washed straw and raw pine wood. The largest influence of K-species was observed in the case of KCl-doped washed straw, showing a significantly lower conversion of fuel N to NO, while for the pine wood, K-doping did not change the conversion of fuel N to NO significantly.
