Abstract—Broadcasting functionality using cross-phase modulation in a nonlinear optical loop mirror utilizing 100-m highly nonlinear (HNL) photonic crystal fiber (PCF) as nonlinear element is demonstrated. This work presents entirely PCF-based network functionalities including broadcasting, transmission, and wavelength conversion. Broadcasting on four channels, transmission of one selected channel through one partially dispersion compensated 10.4-km PCF transmission link and wavelength conversion using four-wave mixing in a 50-m HNL-PCF at the ingress of the target subnetwork have been successfully demonstrated.

Index Terms—All-optical network, broadcasting, photonic crystal fiber (PCF), wavelength conversion.

I. INTRODUCTION

MULTICASTING and broadcasting are essential functionalities in future all-optical networks [1]. For instance, specific information from a given source might have to reach several users located in a number of subnetworks. However, the different subnetworks might be operating on different wavelength sets, and therefore, wavelength conversion at the subnetwork ingress is a basic requirement. In future high-speed optical networks, the various signal processing functionalities will have to be realized in an all-optical way in order to overcome the electrical bottlenecks in the system.

Photonic crystal fibers (PCFs) are very attractive for optical communication since they open new possibilities for the design and fabrication of fibers with tailorable optical properties [2]. For instance, similar structures can be scaled to realize PCFs to be used for either transmission or signal processing purposes [3]. Transmission PCFs can be produced with pure silica core offering low loss [4], large effective area [5], and therefore, reduced fiber nonlinearity, as well as single-mode operation over a large bandwidth [6]. Highly nonlinear PCFs (HNL-PCFs) may offer large nonlinear coefficients and tailorable dispersion properties, and hence are attractive for all-optical signal processing [7].

In this letter, we demonstrate broadcasting, transmission, and wavelength conversion functionalities entirely based on PCFs. For the first time to our knowledge, broadcasting of four channels has been realized using cross-phase modulation (XPM) in a nonlinear optical loop mirror (NOLM) using PCF as the nonlinear element. Broadcast wavelength conversion requires a precise control of the dispersion properties of the HNL fiber, a feature offered by the HNL-PCF design used in this experiment [7]. Transmission to another subnetwork is achieved over 10.4-km transmission PCF, while wavelength conversion at the subnetwork interface is realized by four-wave mixing (FWM) in an HNL-PCF, thus demonstrating a prototype optical network entirely based on PCFs.

II. EXPERIMENTAL SETUP

The experimental setup is shown in Fig. 1. The broadcasting functionality was realized using XPM in an NOLM. The optical information signal at 1558.4 nm controlled the interference at the output of the NOLM (control signal). The information signal was generated by a pulsed laser (Erbium Glass Oscillator Pulse Generating Laser—2-ps pulsewidth) with 10-GHz repetition rate. The pulse train was modulated by a LiNbO₃ Mach–Zehnder modulator at 10 Gb/s into return-to-zero modulation. The pseudorandom bit sequence length was $2^{31} - 1$ bits. A high-power erbium-doped fiber amplifier (EDFA) amplified the control signal to an average output power of 25.2 dBm before it was launched into the NOLM. Four continuous waves (CWs) at wavelengths of 1546.8, 1548.25, 1550.05, and 1551.8 nm with an average power of 0 dBm per channel were also input to the NOLM. In the NOLM, a 100-m-long highly nonlinear fiber (HNL-PCF) with a closely packed cladding structure and a triangular shaped hybrid core, resulting in an effective area of $8 \mu m^2$ served as the nonlinear medium [7]. The nonlinear coefficient of the HNL-PCF was equal to 11 W⁻¹.km⁻¹ and its dispersion was $\sim 3$ ps/(nm·km) at
1550 nm with variations less than 1 ps/(nm-km) over 94 nm. The loss of the 100-m HNL-PCF, including splices to standard single-mode fiber (SMF) pigtailed was 3.3 dB at 1550 nm. At the output of the NOLM, a notch filter eliminated part of the control signal before the four channels were amplified and demultiplexed by an arrayed waveguide grating (AWG) with passbands centered at 1546.92, 1548.51, 1550.12, and 1551.72 nm and with a 3-dB bandwidth of 0.72 nm. This corresponds to the situation where the four multicasted channels would be routed to different subnetworks. One of the channels (at 1548.25 nm) was further transmitted over a partially dispersion-compensated transmission span consisting of 10.4-km transmission PCF and 3 km of conventional dispersion-compensating fiber (DCF) and having a residual dispersion of $-53.9 \text{ ps/(nm}\cdot\text{km)}$ at 1548.25 nm. The transmission PCF had a closely packed structure with a core formed by omitting one central air hole [8]. The spool was spliced from three fiber pieces. The fiber loss was less than 1 dB/km at 1550 nm and its calculated effective area was 64 $\mu\text{m}^2$. Its dispersion was equal to 31.5 ps/(nm-km) at 1550 nm with a dispersion slope of 0.067 ps/(nm$^2$-km). The nonlinear coefficient was measured to be 1.2 W$^{-1}$-km$^{-1}$. After the transmission span, the signal was wavelength-converted (to match the wavelength allocation of the destination subnetwork) using FWM in a 50-m-long HNL-PCF with structure and nonlinear coefficient similar to those of the earlier described 100-m HNL-PCF. The loss of the 50-m HNL-PCF spool, including splices to SMF pigtailed was 2.3 dB at 1550 nm. The dispersion of this HNL-PCF was $-0.6 \text{ ps/(nm}\cdot\text{km)}$ at 1550 nm with a dispersion slope of 0.012 ps/(nm$^2$-km). The signal was amplified and its state of polarization optimized for maximum conversion efficiency before it was input to the HNL-PCF together with a CW light pump with 27.2-dBm average power at 1544.4 nm. At the output of the HNL-PCF, an optical bandpass filter of the FWM product at 1540.34 nm before it was launched into a preamplified receiver consisting of an EDFA followed by a photodiode with 15-GHz bandwidth.

### III. XPM-BASED NOLM WAVELENGTH CONVERTER

The conversion bandwidth of the XPM-based NOLM wavelength converter was first investigated. For this specific measurement, the four CW lasers in Fig. 1 were replaced by an external cavity tunable laser source. The wavelength of the input signal was varied from 1536 nm up to 1556 nm with $\sim$2.5-nm steps. The choice of the exact wavelength was determined by the transfer function of the NOLM. It was ensured that the XPM wavelength conversion was due to the interferometric operation of the NOLM by performing the selection of the converted signal by a tunable bandpass filter perfectly aligned with the converted signal. Eye diagrams of the original NOLM control signal (back-to-back) and the converted signals at wavelengths of 1536, 1546, and 1553.4 nm are shown in Fig. 2.

The distortion due to wavelength conversion was quantified by measuring the power penalty of the converted signal compared to the original control signal to the NOLM at a bit-error rate (BER) of $1.0 \times 10^{-9}$. The power penalty as a function of the wavelength detuning between the control signal and the converted signal is plotted in Fig. 3. Within the investigated 20-nm band, the power penalties of the converted signals were between $-0.3$ and 1.5 dB. Further increase of the detuning range was limited on the short wavelength side by the EDFA gain bandwidth and on the long wavelength side by crosstalk from the control signal.

The obtained good performance over 20-nm bandwidth should permit the wavelength conversion to several wavelengths simultaneously, which in turn will allow the implementation of broadcast functionality.

### IV. RESULTS

Fig. 4 shows the spectra recorded at the NOLM output, at the FWM stage input, and at the FWM stage output. XPM-induced broadening of the four input CW channels is clearly visible on the spectrum recorded at the NOLM output. The spectrum also shows FWM products between the control signal and the four input channels. Due to the requirements on the input signal wavelengths set by the NOLM transfer function and the fixed wavelength allocation of the AWG used to filter out the broadcast channels, the filtering of the channel that was transmitted further is slightly asymmetric. This offset between the center wavelength of the filter and the transmitted channel resulted in slight performance degradation of the broadcasted channel.

In Fig. 5, the eye diagrams of the original control signal of the NOLM (a), the four broadcast channels recorded at the output of the AWG (b)-(e), after propagation through the transmission span including 10.4-km PCF and 3-km DCF and (f) and after wavelength conversion by FWM (g) are shown. The quality of the four broadcast channels is similar. After transmission, dispersion-induced pulse broadening is observable on the pulse.

**Fig. 2.** Eye diagrams of the original NOLM control signal at 1558.4 nm and the wavelength converted signals at the output of the NOLM at wavelengths of 1536, 1546, and 1553.4 nm. Horizontal scale: 20 ps/div.

**Fig. 3.** Power penalty as a function of wavelength detuning between the control signal and the converted signal.
Fig. 4. Spectra recorded at the NOLM output (dashed line), FWM stage input (solid line), and output (dotted line) (resolution bandwidth: 0.01 nm).

Fig. 5. Eye diagrams of (a) the original NOLM control signal, (b)–(e) wavelength converted signals at the output of the AWG, (f) channel at 1548.25 nm after transmission through 10.4-km PCF and 3-km DCF, and (g) at the output of the FWM wavelength conversion stage. Horizontal scale: 20 ps/div.

The FWM wavelength converted pulse is noisy, even though the eye diagram is still wide open.

The BER curves of the corresponding cases have been measured and are plotted in Fig. 6. The back-to-back sensitivity was –29.2 dBm. The power penalties of the four broadcast channels were between 0.9 and 2.4 dB. These penalties are higher than the ones measured when the NOLM has been used to wavelength convert to only one wavelength. The signal degradation compared to the single-channel wavelength conversion is attributed to FWM between the four input signals of the NOLM while they are propagating in the NOLM. The degradation caused by the transmission line is measured to be 0.9 dB. The penalty induced by the FWM wavelength conversion is 0.6 dB.

V. CONCLUSION

We have successfully demonstrated an optical network with functionalities including broadcasting, transmission, and wavelength conversion based entirely on PCFs. Broadcasting on four channels has been realized for the first time using XPM in an NOLM with 100-m highly nonlinear PCF as the nonlinear element. Transmission over 10.4-km transmission PCF and wavelength conversion of a selected channel utilizing FWM in a 50-m-long HNL-PCF have also been successfully demonstrated.
