Keywords: bacteriorhodopsin, biosensors, layer-by layer (LbL) assembly

During the last decades layer-by-layer (LbL) assembly of polyelectrolyte multilayers [1] has emerged as an excellent way to modify and functionalize surfaces. Therefore it has found a great application in a numerous fields including biomimetics, biosensors, tissue engineering, protein and cell adhesion or drug delivery systems [2].

In the present study we investigate the functionality of a biomimetic film composed of cross-linked polyelectrolyte multilayer assembly with incorporated negatively charged polymersoms containing proton driven pump - bacteriorhodopsin. The polyelectrolyte multilayer film prepared by alternating deposition of polyethylenimine (PEI) and poly(styrene sulfonate) (PSS) polyelectrolytes were formed on the porous poly(ether sulphone) PES supporting membrane immobilized via a hydrogel layer on the gold electrode microchip and characterized by means of electrochemical impedance spectroscopy (EIS). Functionality of polymersoms with light induced bacteriorhodopsin was tested by amperometry. The presented data demonstrate that the proposed biomimetic film based on polyelectrolyte assembly on PES support is suitable for membrane protein incorporation and may find an application in construction of biosensors.
