A Wireless Power Transfer (WPT) system is a safe, convenient and smart charging solution for Electric Vehicle (EV) users. However, a drawback of WPT systems is reduced efficiency in comparison to conventional wired charging due to lower coupling. By increasing the volume of EVs in the market, improving the system efficiency even a few percent, beside of being environmentally suitable, will benefit both consumers and distributors. According to the previous studies, efficiency improvement by decreasing the vertical distance (V_D) between transmitter (T_X) and receiver (R_X) coils, has been one of the aims of the companies and universities. However, in low V_D , system performance becomes highly sensitive, due to the magnetic coupling strength. The focus of this paper is to analyze the effects of decreasing the vertical distances to WPT resonance tank efficiency's. Finally, some of the most significant parameters that affect the system efficiency at low V_D such as quality factor and third harmonic interference are analyzed and a mitigating approach is proposed.

Index Terms—WPT; efficiency; mutual inductance; 3rd harmonic impedance interference; reflective resistance

I. INTRODUCTION

WPT technology has a growing market potential, which in the past few years has gained a lot of attention among companies [1-2-3]. There are many companies that are developing the different types of WPT systems such as Qualcomm, Plugless, WitriCity, Delfi, Magna, Maxwell, Panasonic, Daimler, BMW, GM etc. [4-5]. However, there are only a few companies that have been producing the new technologies based on decreasing the vertical distance [6-7], with the aim of increasing the power transfer efficiency, which is the focus of this paper. For instance, the Fraunhofer Institute for Integrated Systems and Device Technology (IISB) with Nose to nose wireless charging method successfully achieved 95% of efficiency [7], and Hughes Electronics that produced the Magne Charge for General Motors by using a magnetic paddle method achieved 86% efficiency [6].

The Magne Charge is an old example of such products with low efficiency. On the other hand, the IISB product has a considerable issue regarding the lack of standardization for placing the coils. While every company placing their transmitter and receiver coils in different places of the EV such as back bottom, middle bottom, front bottom and in the case of IISB is front nose. Thus, their products are self-dependent, which means, the costumers need their own specific charger, transmitter and receiver coils installed and won't be useful with the other applications. This leads to being unsuccessful in the market. However, the idea of decreasing the vertical distance was successful with 95% efficiency. Therefore, setting some international standardization rules for WPT systems seems a necessary task for the worldwide responsible organizations. In this paper, the mutual inductance and the efficiency of the WPT resonance tank in several different vertical distances analyzed to demonstrate the system behavior. The 3rd harmonic interference and the quality factor effects found as complex parameters that should take into consideration as it is presented.

II. WPT MODEL

A. WPT Coil Position Model

In the Figure 1 the coils geometry view is designed to illustrate the coils geometry size and position. As it is shown

in the figure, V_D is the mentioned vertical distance, which is measured from the top surface of the Litz wires to the other side Litz wire surface. Ferrites are including 4 layers of 2 mm thickness and aluminums are also 2 mm thickness layer both in each sides (top and bottom).

Figure 1: Coils Geometry Map

B. WPT Resonance Tank Model

The equivalent circuit model of the WPT system presented in Figure 1, is shown in Figure 2, where, R_p and R_s are the primary and secondary inductor and capacitor internal resistances respectively; M is the mutual inductance; R_{Load} is the equivalent load resistance; Z_p and Z_s are the primary and secondary impedances respectively. The main purpose of this study is analyzing the WPT resonance tank behavior as it defined in Figure 2, while the vertical distance is decreasing.

Figure 2: WPT system schematic

The analyses implemented are based on two different approaches. Firstly, the safe mode analyses, through RLC meter measurements, which are related to applying the low power in the system. This method is providing the study with the main knowledge about the system and its behavior while the magnetic coupling is changing due to the vertical distance

variations. Secondly, the On-Load experimental analysis, which is related to applying the high power in the system. This method is also providing the study a chance to analyze the system behavior under the high power, which is always include some more complexities such as harmonic interferences, and distortions that is discussed in the following sections.

According to the first approach, all of the variable values including the primary and secondary inductances and their internal resistances are measured through the RLC meter in nine different vertical distances ($V_D = 1, 2, 3, 4, 5, 6, 10, 14$ and 18 cm). All measurements have been implemented in the linear sweeping frequency ($1 \text{ kHz} - 130 \text{ kHz}$) to analyze the system behavior. Furthermore, the capacitance values for primary and secondary sides, assumed to be constant ($C_p = C_s = 215 \text{ nF}$) while the project focus is to analyze the system behavior according to coil's vertical distance variations.

C. WPT Equivalent Circuit Model

One of the most important parameters that affect the WPT system's performance is the reflected resistance (R_R) of the system [8]. The R_R , is the equivalent resistance of the load across the primary voltage, which is producing the same amount of current that would flow in the primary side due to the load connected to the secondary. In the Figure 3, the equivalent circuit of the WPT system according to reflective resistance is shown.

Figure 3: Equivalent WPT circuit considering the reflective resistance

According to the Figure 3, the reflective impedance (Z_R), which is including the R_R and reflective reactance (R_X), is calculated through Equation (1). When the system operates in resonance, the value of the R_X is equal to zero [8]. In addition, the values of R_p and R_s are ignored in this calculation since their values are small and negligible comparing to R_{Load} . As long as they influence the efficiency as a form of loss, they are used in the efficiency calculations, which is discussing later.

$$Z_R = R_R + R_X = \frac{\omega^2 \times M^2}{Z_s} + 0 \quad (1)$$

Where, $Z_s = \left(j\omega L_s + \frac{1}{j\omega C_s} + R_{Load} \right)$ is the secondary impedance.

By substituting the above equation to Z_R , when the system operates in resonance $\left(\omega = \frac{1}{\sqrt{L_s C_s}} \right)$, the value of R_R can be calculated through Equation (2).

$$R_R = \frac{\omega^2 \times M^2}{R_{Load}} \quad (2)$$

III. EXPERIMENTAL DISCUSSIONS AND RESULTS

A. Mutual inductance calculation method

In order to measure the mutual inductance of the WPT system, first of all the self-inductances of the system is measured ($L_p - L_s$). Then RLC meter is connected to the coils in two different positions due to the flux linkage direction difference. In this approach, the primary and secondary coils are connected in series in two different coils configuration directions as it is shown in Figure 4(a) and Figure 4(b).

Figure 4: Circuit connections - (a) L+2M; (b) L-2M

When the two coils are connected together as Figure 4(a) configuration, which their flux linkages are in the same direction, i.e. additive [9]; the measurements so called L+2M and the measured value is implemented in the Equation (3) to find the related mutual inductance (M_{L+2M}).

$$L + 2M = L_p + M_{L+2M} + L_s + M_{L+2M} \Rightarrow M_{L+2M} = \frac{L + 2M - L_p - L_s}{2} \quad (3)$$

Similarly, the same approach is implemented to calculate the mutual inductance correspond to L-2M (Figure 4(b)), which the flux linkages of the coils are in opposite directions and is used to calculate the related mutual inductance (M_{L-2M}).

$$L - 2M = L_p - M_{L-2M} + L_s - M_{L-2M} \Rightarrow M_{L-2M} = \frac{L - 2M - L_p - L_s}{-2} \quad (4)$$

According to the measurements, the mutual inductances of the specific V_D at the specific switching frequency are achieved. This approach named as L+2M and L-2M. The average of both measurements will be count as an achieved mutual inductance as Equation

(5). This is due to the accuracy and preventing from the hysteresis loss, which can cause different value of mutual inductances following different coils turning direction.

$$\bar{M} = \frac{M_{L+2M} + M_{L-2M}}{2} \quad (5)$$

Based on the presented calculation approach, all the measured values are implemented into the explained equation through Matlab and plotted out to illustrate the mutual inductance behavior while the V_D is decreasing. According to the results, the mutual inductance, behaves as a constant value in the frequency range used in the experiments. Hence, Figure 5 is used to illustrate the mutual inductance variation as a function of V_D , at $f_r = 21.5 \text{ kHz}$. As it is shown, the mutual inductance increases significantly by decreasing the V_D .

Figure 5: Mutual inductance in different V_D at $f_r = 21.5 \text{ kHz}$

B. Fundamental Based Efficiency Analyses

According to the mutual inductance analyses, it can be seen that by decreasing the V_D , the magnetic coupling strength is significantly increasing, which is affecting the system efficiency and some other elements. Therefore, through the efficiency (η) Equation (6) [8-10], the maximum efficiency of 97.36%, at $V_D = 1\text{cm}$ at $f_r = 21.5\text{kHz}$, has been achieved for the WPT resonance tank, which is shown in Figure 6.

$$\eta = \eta_p \times \eta_s = \frac{\frac{\omega^2 \times M^2}{R_s + R_{Load}}}{R_p + \frac{\omega^2 \times M^2}{R_s + R_{Load}}} \times \frac{R_{Load}}{R_s + R_{Load}} \quad (6)$$

Where: η_p and η_s are the efficiencies of primary and secondary side of the resonance tank respectively; $R_{Load} = \frac{\omega_r \times L_s}{Q_s}$ is the load equivalent resistance; L_s is the secondary coil inductance; Q_s is the quality factor of the secondary side, which is assumed to be $Q_s = 4$ as it is shown in Figure 6.

Figure 6: Efficiency plot of WPT resonance tank at $Q=4$

C. 3rd Harmonic Impedance Interference

By applying power to the system at the vertical distances below four centimeters, the system became interfered with the third harmonic impedance (Z_{3rd}). One of the general consequences of the Z_{3rd} in the system is the electromagnetic interference (EMI) that can affect the other nearby sensitive electronic devices' operation. However, the main consequence of this interference is decreasing the efficiency through higher harmonic current in the system.

Basically, in a WPT system, the first harmonic is the fundamental harmonic that will be used to transfer the power. The 2nd harmonic and all even order harmonics are not in the system because the input voltage has square wave symmetry; hence, it will be equal to zero. The third harmonic is the undesired harmonic that interferes with output power and has to be eliminated. Based on the studies in [8], the performance of the WPT resonance tank is highly dependent on the R_R in the way that has to stay in maximum level of Z_R , otherwise it will damp the resonance in the system. In the case we are studying, this effect appears as the Z_{3rd} .

In order to prevent the system from this interference, it is important to clarify in which circumstances the system becomes interfered and when it will get back to the normal state. Based on the studies done in this project, it is shown that the system is interfered due to decreasing the quality factors (Q_p and Q_s) of the system below the minimum. According to the analyses, the bandwidth of the system is equal to $BW = 10$

kHz and $f_r = 21.5\text{kHz}$. Therefore, the minimum quality factor of the system can be calculated through Equation (7).

$$Q = \frac{f_r}{BW} = \frac{21.5}{10} = 2.15 \quad (7)$$

On the other hand, the primary Q can be computed through Equation (8).

$$Q_p = \frac{\omega_r L_p R_{eq}}{\omega_r^2 M^2} = \frac{\omega_r L_p}{R_R} = \frac{x_{L_p}}{R_R} \quad (8)$$

Through the discussion it is clear, which to keep the Equation (7) hold true, the value of x_{L_p} have to stay two times bigger than R_R . In Figure 7, the variability of two R_R based on ($Q=2$ and 4), versus x_{L_p} in different vertical distances, is illustrated. By considering the green line ($Q=2$) in comparison to red (x_{L_p}), it can be seen that x_{L_p} is greater than $2 \times R_R$ at $V_D > 4\text{cm}$.

Figure 7: x_{L_p} vs. R_R as a domain of V_D

As long as Z_{3rd} is proportional to the correspond third harmonic current (I_{3rd}), when this value decreases, the value of I_{3rd} will increase. Therefore, if Z_{3rd} decreases to the point that Equation (7) would not hold true, thus the results will appear in the output as an interference. In the Figure 8, the efficiency of transferred power is 3D plotted in terms of frequency and vertical distances for the quality factor of four. As it can be seen, the interferences are continuing up to $V_D = 10\text{cm}$.

Figure 8: 3D plot of transferred power as a domain of frequency and V_D at $Q=4$

D. On-Load Analyses

According to the analyses, it is expected to have the 3rd harmonic interference in the vertical distances below $V_D = 4\text{cm}$. Therefore, the experimental analyses have been made to prove the theoretical results. Firstly, Figure 9 is captured, which is the oscilloscope screen and the results of applying

power at $V_D = 1\text{ cm}$ and the operating resonance frequency calculated for the specific V_D that is $f_r = 18.065\text{ kHz}$. Through the figure, it is clear that Z_{3rd} is interfering with the both primary and secondary currents differently. This is due to the different quality factors in both sides, which leads to Z_{3rd} behaving differently.

Figure 9: Third harmonic interference at $V_D = 1\text{ cm}$

Several more experiments have been implemented to prove the quality factor effects and illustrate the interference in the system. In Figure 10, which is the results of applying power at $V_D = 4\text{ cm}$, $f_r = 20.367\text{ kHz}$, $Q_P = 2.53$ and $Q_S = 1.28$, it can be seen that the interferences are decreased significantly and the primary quality factor, tuned to stay over two for the Q_P , which leads to the primary current with no interference, while the secondary quality factor is less than two and secondary current is interfered. Furthermore, the quality factors for Figure 11 is tuned for $Q_P = 1.26$ and $Q_S = 2.66$, resulting in the currents behaving oppositely.

Figure 10: $V_D = 4\text{ cm}$, $Q_S < 2$, $Q_P > 2$ and I_S interfered

Figure 11: $V_D = 4\text{ cm}$, $Q_S > 2$, $Q_P < 2$ and I_P interfered

IV. CONCLUSION

Based on the results, we can conclude that, in order to keep the system with no interference the quality factors of the system have to stay at least over two in the tight coupling applications. The significance of the Q and R_R has been discussed. According to the R_R equation, it can be seen that by decreasing the vertical distance, the mutual inductance increases significantly, which leads to increasing the R_R . This increment will damp the resonance in the system, which leads to less efficiency. Therefore, the x_{L_p} will be smaller than the R_R value in the distances below four centimeters, which also leads to the interference in the system.

Mainly, by decreasing the coil geometry size, the coil self-inductance will decrease [11]. Therefore, one of the effective approaches to reduce the mutual inductance in low vertical distances is to reduce the secondary coil geometry to smaller size, which is leading to smaller secondary self-inductance and thus smaller mutual inductance. However, smaller secondary coil requires new design based on the new coil's configuration.

Finally, reducing the coil geometry will cause a lot of the benefits such, the costs of the Litz wire and ferrite will be less, the occupied space on EV will be less etc.

Furthermore, these results are case dependent and might not apply in the other WPT setups, which have different designs.

ACKNOWLEDGMENT

Hereby, I would like to thank Dr. Erik Schaltz; and Aalborg University (AAU), which gently gave me the opportunity to work on their WPT setup and offered me the necessary equipment to make the measurements and analyses. A special thanks also to Dr. Luiz A. de S. Ribeiro, with his friendly advises and technical supports.

This project is supported by Denmark's Technical University (DTU), Department of Electrical Engineering, under the supervision of Dr. Ziwei Ouyang, Prof. Michael A.E. Andersen and Dr. Peter B. Andersen.
