Abstract
Qudi is a general, modular, multi-operating system suite written in Python 3 for controlling laboratory experiments. It provides a structured environment by separating functionality into hardware abstraction, experiment logic and user interface layers. The core feature set comprises a graphical user interface, live data visualization, distributed execution over networks, rapid prototyping via Jupyter notebooks, configuration management, and data recording. Currently, the included modules are focused on confocal microscopy, quantum optics and quantum information experiments, but an expansion into other fields is possible and encouraged.

1. Motivation and significance

Modern scientific experiments typically rely on multiple hard-
ware devices working together in a coordinated fashion. In many
instances, the hardware devices are commercial products with
programming interfaces for direct control via custom software. The
unique combination of such devices is then specific to a given ex-
periment. Efficient control of such experiments requires software
that is capable of coordinating the operation of multiple devices. In
addition, data interpretation is facilitated by rapid data processing
and visualization.

The software is used for such experiments, but there is a paucity of mature
and flexible lab control software to operate the apparatus.

Here, we present Qudi, a Python software suite for controlling
complex experiments and managing the acquisition and processing
of measurement data. Despite being developed in the context of
quantum optics laboratories, the core Qudi framework is broadly
applicable to many scenarios involving coordinated operation of
multiple experiment devices. The free and open-source nature of
Qudi makes it possible for anyone to use and modify the software
to fit their research needs, and the modular code design simplifies
this task. Qudi continues to be actively developed, but it is already
mature enough for reliable laboratory use [11].

2. Software description

2.1. Why Python?

Python was chosen as the programming language for Qudi be-
cause of its conceptual synergy with the goals of the project. As a
dynamic, strongly typed, scripting language, Python has become
a popular choice for scientific programming [12,13] as the impor-
tance of scientific software increases [1–4]. Python’s high level of
abstraction makes it human-readable and concise, providing a di-
rect advantage for laboratory programming typically performed
by scientists rather than dedicated software developers. Source
code availability under an open-source license, the built-in mod-
ular structure of Python and good community support lower the
initial hurdle to learn the language. Additionally, most laboratory
hardware has at least an application programming interface (API)
specified for the C programming language, which can be accessed
by Python.

2.2. Qudi design

The Qudi suite consists of a collection of modules that are loaded
and connected together by a manager component according to set-
tings given in a configuration file as shown in Fig. 1(a). The program
startup code and manager were initially derived from similar ele-
ments contained within the neurophysiology software ACQ4 [16].
Startup is initiated by a single executable python file, and the man-
ger component provides core functions for logging, error han-
dling, configuration reading, and remote access. Additionally, the
manager also administers the other modules by providing func-
tionality for module loading, module dependency resolution and
connection, concurrent execution and network access to modules
running on other computers. This core infrastructure makes it eas-
ier to rapidly develop modules for new experiments by providing
structure and starting points.

A typical Qudi session will proceed as follows. On startup, the
supervisor process, for example an IDE, creates a Qudi process. In
this Qudi process, the manager component reads the configuration
file, sets up the log file and loads the modules designated in the
startup section of the configuration file. Typically, the startup sec-
ction will – but does not have to – contain at least the Manager GUI
and the tray icon module. Laboratory operation and experiment
control are performed by science modules, which are specified in
the configuration file along with any hardware-specific parame-
ters. Science modules can be loaded for the desired measurement
from the Manager GUI or a Jupyter notebook. Some of the science
modules in Qudi were inspired by the pi3diamond software [3–5,
17–19].

The science modules are divided into three categories: hard-
ware interaction, experiment “logic”, and user interface. These
categories and the relationships between them are illustrated in
Fig. 1(b). The division into hardware, logic, and interface represents
a clear separation of tasks that improves reliability and flexibility
of the Qudi code. It also simplifies the implementation of new ex-
periment modules. The fundamental three-fold distinction is the
basis of Qudi’s adaptability, and makes Qudi an experiment control
software in contrast to a general software framework.

2.2.1. Logic modules

Logic modules control and synchronize a given experiment. They pass input parameters from the user interface to
the respective hardware modules, and process measurement data in
the desired way. These modules control the information exchange

Scripting languages cannot replace established compiled pro-
gramming languages for tasks where processing performance or
memory efficiency is required but they are very useful to glue
together different components in order to benefit from the ad-
vantages each of them can offer [15]. This is closely aligned with
the concept of Qudi “gluing” together various devices and control
methods for specific complex experiments.
between different hardware modules and perform all necessary computations and conversions.

Logic modules are the only type of modules that are allowed to interact with each other. They are also the only type of module that has its own thread and event loop. Therefore they are the place where concurrent execution of tasks and synchronization of different devices is handled. All steps from the start of a measurement to its end, including data evaluation and storage are performed by the logic. This goes as far as producing “publication ready” plots of data that are saved together with the raw data and which provide a good overview or can be sent to collaborators without post-processing.

2.2.2. Hardware abstraction via interfaces

Today it is possible and even necessary to control most experiment hardware remotely. Unfortunately, the command structure, grammar, measurement units and connection methods differ widely between device models or devices from different suppliers of experiment hardware. To get the most re-usability out of logic modules, it must be possible to interchange hardware modules for measurement devices that provide similar functionality, but work and communicate differently. It is the task of the hardware modules to overcome these problems by translating the commands given by the logic into the “language” of the specific hardware.

The problem is solved by defining an interface, a set of functions that a hardware module of a given type must implement, in order to make a certain measurement work. This set of functions is defined in a class (named ...Interface in a file in the interface folder) where the default implementation of each function raises an exception, if it is not replaced in the device-specific implementation. This class is then inherited by the actual implementing hardware module and all inherited functions must be overwritten.

Hardware modules can represent virtual dummy or mock hardware, which emulates the functionality of a device. Those dummies could load recorded measurement files, create arbitrary data or may perform real physical simulations of measurements, where the result is prepared according to the interface commands which the logic can access. One of the most significant uses of dummy hardware modules is to test the experiment logic without being connected to any actual hardware.

2.2.3. Advanced abstraction via “interfuses”

Building on the abstraction of interfaces, Qudi introduces an additional concept to facilitate the reuse of modules. This ability is provided by interfuse modules which interconnect (or fuse) different hardware or logic modules to modify their interface behavior or to achieve a task for which these modules were not originally designed.

An interfuse is a logic module that implements a hardware interface. In doing so, it pretends to be hardware that can connect to an experiment logic module. This allows the core experiment functions to remain in the logic module, while altering the kind of data that is measured. A tangible example helps clarify this concept. A confocal image (2D array) can represent single fluorescence values from a photon counter for each position \((x, y)\). An interfuse makes it possible to replace the counter data with spectrometer measurements at each pixel, allowing fluorescence to be imaged with arbitrary spectral filtering. This practice improves maintainability and prevents code duplication.

The other reason to use interfuses is where a desired feature would require altering an existing interface definition. For example, an interfuse can perform the coordinate transform to correct for a tilted sample in a confocal scan. As a result, the tilted surface appears flat in the confocal image and can then be imaged at a consistent depth.

2.2.4. GUI

Qudi GUI modules create windows on the screen that a user can interact with, allowing experiment control and data visualization. Their purpose is to offer a convenient way for the user to interact with logic modules, however Qudi is fully functional without the GUI modules. The logic can also be controlled by the integrated IPython console or from a Jupyter notebook. For this reason, GUI modules are not allowed to interact with each other or the hardware directly and they do not data processing.

The Qudi graphical user interface (GUI) is built with Qt [20], offering users a familiar appearance. Qt is suitable due to its multi-platform GUI toolkit that provides good Python bindings [21,22] and makes it possible to separate the GUI design from the implemented functionality. Also, Qt’s multi-thread ability ensures good scalability and parallel processing, which are essential requirements for complex experiments. Furthermore, Qt implements a signal-slot mechanism [23] that is very useful for
concurrency, modular design, and interaction between GUI modules and logic modules. On top of this, the Python library PyQtGraph [24] makes it easy to create interactive, frequently updated 2- and 3-dimensional plots.

The user interface can be edited graphically in Qt Designer and stored as an XML file. For rapid prototyping, this file can be (re)loaded by a running Python program. The GUI design strives to adhere to the KDE Human Interface Guidelines [25], as these stress the importance of interface familiarity and they work well with the default set of Qt user interface elements.

2.2.5. Interactive scripting

Interactive scripting provides a powerful additional user-interface for a flexible software suite. Qudi contains a built-in console with a fully integrated IPython interpreter. In addition, Qudi can be controlled from a Jupyter Notebook. This makes it possible to write a scripted document with incremental execution as well as inline visualization and analysis. Both the console and the Jupyter notebook can control all of the internal states of the Qudi software. These features enable rapid experiment prototyping, since a developer can test different approaches before committing to changes in hardware or logic modules.

3. Impact and reuse potential

The Qudi suite is useful for any small to medium-size computer-controlled laboratory experiment. Its modular design combined with the use of interface definitions makes it easy to integrate new hardware into an existing experiment. Moreover, this design offers the capability to easily reuse existing modules in new experiments. The Qudi core infrastructure is broadly applicable, even beyond the context of confocal microscopy or physics experiments in general.

Qudi is of more tangible impact to the quantum optics community in particular. The existing modules already offer control over confocal microscopes, electromagnets, motorized stages, lasers, (arbitrary) signal generators, and other devices used in this field of research. Table 1 lists the science modules currently included in the Qudi suite. Furthermore, typical measurement protocols and data analysis functions are already implemented. These existing modules make Qudi a ready-to-use Python-based software suite for quantum optics labs, independent from the individual hardware and measurement schemes used by different groups.

4. Illustrative example

The measurement of optically detected magnetic resonance (ODMR) on single color centers in diamond [26,27] requires the coordinated operation of a scanning confocal microscope and a microwave source. This section describes how such a measurement is performed with Qudi, illustrating the convenience arising from the software design outlined in this paper. The interested reader can perform this process using the default config distributed with Qudi that loads dummy hardware modules to provide representative data. This experiment makes use of the "confocal" and "ODMR" science modules.

The first step is to find a single color center inside the diamond. The Qudi confocal GUI and logic modules are used to move a diffraction-limited focal spot through the diamond sample in three dimensions [28–31]. This is achieved by scanning hardware that is controlled by the confocal logic. A photon counter records the fluorescence measured by the confocal microscope, and this hardware device sends the data to the confocal logic. The confocal logic produces an image of fluorescence as a function of position, and the GUI presents this image to the user. Fig. 2 shows the confocal GUI with an x–y image on the left and an x–z image on the right.

In order to focus on a single center, the user places the confocal cursor near a promising spot. An optimizer module performs a series of close-range scans around the cursor, and the optimal position of maximum fluorescence is found via a fitting module built on the lmfit package [32]. A 2D Gaussian fit is performed on the x–y plane scan and for the third dimension a 1D gaussian fit on the z line scan. These are shown in Fig. 2 on the lower right of the Confocal GUI. Finally, the optimizer module moves the scanning hardware to the optimal position focused on the desired single color center.

In addition to spatial alignment, a microwave resonance condition has to be matched in order to detect the desired change in optical signal [26,27,33–35]. The ODMR logic module controls the frequency of a microwave source while recording the fluorescence level. The design of Qudi means that the ODMR logic is easily capable of driving a variety of microwave source hardware, increasing flexibility in the laboratory.

An ODMR experiment is performed by sweeping the microwave frequency and recording the fluorescence. Recorded data are shown live on screen in the ODMR GUI as both the fluorescence sum of all frequency sweeps and as a matrix plot containing each sweep (Fig. 2, lower right). ODMR scans of several spots can be measured automatically by saving the color center positions and then using a script to move from spot to spot, optimizing the position on each site and recording an ODMR spectrum.

5. Conclusions and future directions

Qudi is a generally applicable experiment control software suite, with infrastructure to support modular design of experiments, significantly reducing the effort involved in constructing new experiments. Qudi already offers a developed quantum-optics tool set capable of reliable laboratory operation, and a modern user interface.

There is continuing effort to expand the library of available science modules. One priority for the future is to simplify the setup of Qudi by providing a graphical configuration editor. Furthermore, it would be convenient to make Qudi installable from the Python
