Citation (APA):
We present the development of a detection strategy based on surface-enhanced Raman spectroscopy (SERS) sensing in liquids, relevant for biological samples. The SERS substrates, fabricated from free-standing, gold-capped silicon nanopillars are commonly used for the detection of analytes dissolved in organic solvents and dried on the sensor surface. We developed a method where detection can be performed directly in liquid using a model drug acetoaminophene (Paracetamol).

### SERS Sensing in Cell Models

**Intestinal Cell Model - Transwell® Systems**

Caco-2 cells, are widely used as *in vitro* intestinal model. [2] Transwell® systems are used in *in vitro* drug permeation studies, where drugs are added to the transport media (e.g. Hank’s balanced salt solution (HBSS)). Samples are commonly analyzed with robust, but time and resource consuming techniques such as high-performance liquid chromatography. (Bio)sensors based on SERS offer fast, accurate and cost effective alternatives for identifying drug types and concentrations in permeation studies.

**SERS Substrates – Gold Capped Nanopillars**

SERS is a powerful analysis technique capable of detecting molecular fingerprints of analytes with high sensitivity and fast response time. [3]

Classical dry droplet SERS sensing using gold-capped Si nanopillars. [4]

**Droplet SERS**

Dry droplet SERS-based detection of paracetamol. Dry droplet measurements are highly influenced by solvent composition. Complex matrices like HBSS can lead to fouling of the sensors. To enable droplet measurements it was necessary to dilute HBSS 1:10 with pure ethanol.

![Droplet SERS Image](image)

Paracetamol spiked in pure ethanol and HBSS. Calibration curves were obtained following the characteristic paracetamol peak at 1160 cm⁻¹. We found that Paracetamol dissolved in ethanol can be detected in a linear range between 35 - 200µM, while when spiked in HBSS and diluted 1:10 with ETOH a linear trend between 50 – 350µM is observed.

### Surface Treatment

UV/ozone exposure is commonly utilized as surface treatment and cleaning procedure in a variety of microfabrication processes. It renders the surface of gold-capped nanopillars from hydrophobic to hydrophilic without any morphological alterations.

![Surface Treatment Image](image)

Liquid Measurements

UV/ozone treatment enabled the development of a novel liquid measurement technique for nanopillar SERS based sensing.

![Liquid Measurements Image](image)

Detection of 350 µM paracetamol in liquid UV/Ozone treated samples.

Paracetamol spiked in MQ and HBSS. Liquid detection of paracetamol in MQ is possible over a linear range of 5–100µM. Direct liquid measurements in HBSS displayed a linear trend between 5–75 µM.
