Contamination of the Arctic reflected in microbial metagenomes from the Greenland ice sheet—Letter

Globally emitted contaminants accumulate in the Arctic and are stored in the frozen environments of the cryosphere. Climate change influences the release of these contaminants through elevated melt rates, resulting in increased contamination locally. Our understanding of how biological processes interact with contamination in the Arctic is limited. Through shotgun metagenomic data and binned genomes from metagenomes we show that microbial communities, sampled from multiple surface ice locations on the Greenland ice sheet, have the potential for resistance to and degradation of contaminants. The microbial potential to degrade anthropogenic contaminants, such as toxic and persistent polychlorinated biphenyls, was found to be spatially variable and not limited to regions close to human activities. Binned genomes showed close resemblance to microorganisms isolated from contaminated habitats. These results indicate that, from a microbiological perspective, the Greenland ice sheet cannot be seen as a pristine environment.

General information
Publication status: Published
Organisations: Novo Nordisk Foundation Center for Biosustainability, Department of Bio and Health Informatics, Department of Biotechnology and Biomedicine, Metagenomics, DTU Multi Assay Core, Geological Survey of Denmark and Greenland, Chr. Hansen AS, Clinical-Microbiomics ApS, Charles University
Contributors: Hauptmann, A. Z. E. L., Sicheritz-Pontén, T., Cameron, K. A., Bælum, J., Plichta, D. R., Dalgaard, M. D., Stibal, M.
Number of pages: 10
Publication date: 2017
Peer-reviewed: Yes

Publication information
Journal: Environmental Research Letters
Volume: 12
Issue number: 7
Article number: 074019
ISSN (Print): 1748-9326
Ratings:
BFI (2017): BFI-level 1
Scopus rating (2017): CiteScore 4.83 SJR 2.436 SNIP 1.548
