Experimental and Numerical Study of Wave-Induced Backfilling Beneath Submarine Pipelines

Experimental and Numerical Study of Wave-Induced Backfilling Beneath Submarine Pipelines

Through complementary experimental and numerical efforts, the present paper aims to make a significant contribution to the overall understanding of backfilling processes beneath submarine pipelines. For this purpose, we aim to simplify the experimental backfilling process to an elementary two-stage process: (1) initial scour induced by a pure current, followed by: (2) backfilling induced by pure waves. A steady current is introduced via a recirculating pump, and is kept constant with a cross-sectional velocity of \( V = 0.48 \) m/s until an initial equilibrium scour depth, \( S_0 \), is reached. Then, the current is stopped and waves (characterized by their Keulegan-Carpener number \( KC \) and Shields parameter \( \theta \)) are introduced to initiate the backfilling process, which is maintained until a new equilibrium scour depth, \( S_f \), is reached. The time at which waves are introduced will be denoted as \( t = 0 \). For the backfilling process both regular and irregular waves are used during the experiments. As a demonstration of the initiated two-stage (scour followed by backfilling) process, bed profiles based on video recordings from a case having \( KC = 9.7 \) and \( \theta = 0.195 \) are depicted at selected stages in Figure 1. Figure 1 (upper left) depicts the current-induced equilibrium scour hole in the near vicinity of the pipe at \( t = 0 \), with the profile approximated as the dashed red line. Similarly, Figure 1 (upper right) depicts the new equilibrium scour profile (approximated as the full blue line) that has developed under wave-induced backfilling, corresponding to \( t = 60 \) min. To ease comparison, the dashed red and full blue lines from these plots are additionally combined onto Figure 1 (bottom). The experimental campaign has additionally been complemented with similar numerical simulations (using regular waves), based on a fully-coupled hydrodynamic and morphodynamic CFD model (Jacobsen et al., 2014), extending previous pipeline scour-related applications of Fuhrman et al. (2014) and Larsen et al. (2016). Comparison of the numerical and experimental results demonstrate the ability of the CFD model to reasonably simulate the current-to-wave backfilling process, both in terms of the achieved new wave induced equilibrium scour depths as well as the corresponding backfilling timescales. Figure 2 depicts a summary of both experimental and numerical backfilling time scale \( T_b \) versus Shields parameter \( \theta \). As can be seen, both experimental as well as numerical results match the regression equation \( T_b = 0.3 \theta^{-0.5} \) quite closely (solid line in Figure 2).

General information

Publication status: Published
Organisations: Fluid Mechanics, Coastal and Maritime Engineering, Department of Mechanical Engineering, Technical University of Denmark
Contributors: Bayraktar, D., Ahmad, J., Larsen, B. E., Carstensen, S., Fuhrman, D. R.
Number of pages: 1
Publication date: 2016
Peer-reviewed: Yes
Event: Abstract from 35th International Conference on Coastal Engineering (ICCE’16), Antalya, Turkey.
Electronic versions: 1317.pdf
Research output: Contribution to conference › Conference abstract for conference – Annual report year: 2016 › Research › peer-review
