The crustal uplift determined at the Jakobshavn glacier (West Greenland) using ATM and GPS data - DTU Orbit (10/11/2019)

The crustal uplift determined at the Jakobshavn glacier (West Greenland) using ATM and GPS data

The Greenland ice sheet has experienced record melting in recent years. In order to estimate the ice loss we can make use of the earth's natural elasticity to weigh the ice. Ice bends down the bedrock so when the ice melts away, the bedrock rises measurably in response. Throughout this abstract we present both a predicted and observed crustal uplift for the Jakobshavn glacier using ATM data (Airborne Topographic Mapper) from NASA ATM flights during 1997, 2005 and 2010 supplemented with data provided from continuous Global Positioning System (GPS), measurements made on bedrock between 2005-2010.

In order to compute the crustal uplift in response to the ice mass loss of the Jakobshavn area from the GPS stations, the convolution of the gridded thinning rates has been computed with the vertical-displacement Green's function as described in [1].

Several manipulations of data were required in order to achieve a good prediction of the crustal uplift. In this sense the programs Matlab and Geogrid-Gravsoft were used along with some Fortran executable files. Furthermore, the GPS data which presents the difference in uplift is provided processed as a difference of data from the permanent GPS stations KAGA, ILUL and QEQE relative to the AASI station (Figure 1). Also, in order to compare the predicted uplift from ATM data with the observed uplift from GPS data the post-glacial rebound (PGR) rates have been subtracted.

The results obtained for the predicted crustal uplift for KAAS is 11.62 mm/yr while the observed value was 16.321 mm/yr, for ILAS 1.74 mm/yr and 1.53 mm/yr, for QEAS-0.189 mm/yr and 1.15 mm/yr. That being an difference of 4.701 mm/yr is found for KAAS, 0.21 mm/yr for ILAS and 1.399 mm/yr for QEAS. The uncertainties associated both with the ATM and GPS results are 0.8 mm/yr for ATM and 0.5 mm/yr for GPS. The total ice mass loss in km$^3$ of water predicted from the ATM data concerning the Jakobshavn area is -88.815 between 2010 and 2005 and -83.599 between 2005 and 1997.

It seems fair to state that these differences, between the predicted and observed rates, may also be due to the fact that not all the errors have been taken into account when computing the observed results and also due to the fact that, perhaps, ice is melting in Greenland much faster than predicted.

General information
Publication status: Published
Organisations: Department of Applied Mathematics and Computer Science, Statistics and Data Analysis, National Space Institute, Geodesy
Contributors: Muresan, I. S., Frumosu, F. D., Khan, S. A.
Number of pages: 1
Publication date: 2012
Peer-reviewed: Yes
Electronic versions: ThecrustalupliftdeterminedattheJakobshavn.pdf
Research output: Contribution to conference › Conference abstract for conference – Annual report year: 2012 › Research peer-review
