INTRODUCTION Extreme climate events are projected to be among the future most challenging constraints to plant development. Heatwaves as well as floods and droughts cause acute changes in the growth environment determining our primary production (Collins et al., 2013). Europe experienced extreme heatwaves in 2003 and 2006. In 2003, a 21% decrease in the French wheat production was found from temperatures up to 6 °C above long-term means and precipitation being less than 50 % of the average (Ciais et al., 2005). One strategy to mitigate the decreases from heatwaves is to identify resilient cultivars and incorporate them in breeding programs.

EXPERIMENT Four basic treatments with projected levels of temperature and [CO₂] as might be expected at the end of this century (~RCP8.5; IPCC, 2013) was applied as single factors or in combination throughout the growing period (Fig. 1). At the time of flowering a 10 day-heatwave of 33/28 °C (day/night) was superimposed on the treatments (Fig. 1). At maturity plants were harvested and threshed individually and grain, vegetative biomass, harvest index (HI) and grain yield per ear were determined.

RESULTS The applied heatwave decreased grain yield with the strongest decrease in the treatment with elevated [CO₂] (43%; Fig. 2). However, vast variation existed between accessions (Fig. 3). In the treatment of elevated temperature and [CO₂] combined, the superimposed heatwave decreased grain yield of accessions 2-80 %. The heatwave further changed allocation by increasing aboveground vegetative biomass. The most likely future climate scenario of elevated temperature and [CO₂] in combination and with the superimposed heatwave was found to decrease overall grain yield by 52 % compared to present day conditions.

CONCLUSION The identified variation in the set of barley accessions in response to multifactor climate treatments was high as such, however, the ability to cope with heatwaves and avoid severe yield losses of less than 29 % was not identified in the accessions included. In fact, these results emphasize the threat that temperature extremes exert to crop production systems.
