Chemoselective hydrogenation of arenes by PVP supported Rh nanoparticles

Mahmoud Ibrahim, Raju Poreddy, Karine Philippot,* Anders Riisager* and Eduardo J. Garcia-Suarez*

Polyvinyl pyrrolidone-stabilized Rh nanoparticles (RhNPs/PVP) of ca. 2.2 nm in size were prepared by the hydrogenation of an organometallic complex [Rh(η3-C3H5)3] in the presence of PVP and evaluated as a catalyst in the hydrogenation of a series of arene substrates as well as levulinic acid and methyl levulinate.

Please check this proof carefully. Our staff will not read it in detail after you have returned it.

Translation errors between word-processor files and typesetting systems can occur so the whole proof needs to be read. Please pay particular attention to: tabulated material; equations; numerical data; figures and graphics; and references. If you have not already indicated the corresponding author(s) please mark their name(s) with an asterisk. Please e-mail a list of corrections or the PDF with electronic notes attached – do not change the text within the PDF file or send a revised manuscript. Corrections at this stage should be minor and not involve extensive changes. All corrections must be sent at the same time.

Please bear in mind that minor layout improvements, e.g. in line breaking, table widths and graphic placement, are routinely applied to the final version.

We will publish articles on the web as soon as possible after receiving your corrections; no late corrections will be made.

Please return your final corrections, where possible within 48 hours of receipt, by e-mail to: dalton@rsc.org

Chemoselective hydrogenation of arenes by PVP supported Rh nanoparticles

Mahmoud Ibrahim, Raju Poreddy, Karine Philippot, Anders Riisager and Eduardo J. Garcia-Suarez

Polyvinyl pyrrolidone-stabilized Rh nanoparticles (RhNPs/PVP) of ca. 2.2 nm in size were prepared by the hydrogenation of an organometallic complex \([\text{Rh}(\eta^3-\text{C}_3\text{H}_5)_3]\) in the presence of PVP and evaluated as a catalyst in the hydrogenation of a series of arene substrates as well as levulinic acid and methyl levulinate. The catalyst showed excellent activity and selectivity towards aromatic ring hydrogenation compared to other reported transition metal-based catalysts under mild reaction conditions (room temperature and 1 bar \(\text{H}_2\)). Furthermore, it was shown to be a highly promising catalyst for the hydrogenation of levulinic acid and methyl levulinate in water leading to quantitative formation of the fuel additive \(\gamma\)-valerolactone under moderate reaction conditions compared to previously reported catalytic systems.

Introduction

The hydrogenation of aromatic C–C double bonds to form cyclohexane derivatives is one of the most important reactions in both petrochemical and pharmaceutical industries. For instance, the chemoselective hydrogenation of benzoic acid to cyclohexane carboxylic acid\(^1\) is a crucial step in the fiber industry for the synthesis of \(\varepsilon\)-caprolactam from toluene in the Snia Viscosa process (developed by SNIA S.p.A., Italy).\(^2\)

Furthermore, cyclohexane carboxylic acid is a key intermediate in the synthesis of pharmaceuticals in high demand such as praziquantel and ansatrienin (Fig. 1).\(^3\)–\(^5\)

The high relevance of benzoic acid hydrogenation in both bulk and fine chemical industries has attracted a lot of attention from the scientific community to develop catalysts for the chemoselective hydrogenation of benzoic acid to cyclohexane carboxylic acid. However, hydrogenation of aromatic C–C double bonds, compared to olefinic C–C double bonds, is a very challenging transformation since it generally requires severe reaction conditions. Moreover, a selective catalyst is needed which only hydrogenates the aromatic ring while keeping other functional groups present in the molecule intact. Noble transition metal catalysts, either homogeneous or heterogeneous systems, including Ru–Pt, Rh/C, Pd/C, and Pd–Ru have been extensively studied for arene hydrogenation and generally found to exhibit high activities.\(^2,6\)–\(^9\) Among them, Rh/AC (AC = activated carbon) and Pd/AC catalysts show superior catalytic activity compared to other supported transition metal catalysts.\(^10\) Pd/AC are traditionally used for \(\varepsilon\)-caprolactam production in the chemical fiber industry\(^11\) and for terephthalic acid refining in the polyester industry.\(^12\)

It is worth pointing out that the process of benzoic acid to cyclohexane carboxylic acid hydrogenation with Pd/AC catalysts suffers from a number of limitations, i.e. high temperature (150 °C) and high \(\text{H}_2\) pressure (150 bar) conditions as well as excessive catalyst consumption due to its fast deactivation.\(^13\) Tsung \textit{et al.} have recently reported that Pt nanocrystals are catalytically active in the hydrogenation of pyrrole to \(n\)-butylamine and that both the activity and the selectivity strongly depend on the shape and size of Pt nanocrystals.\(^14\) A similar behavior was observed by Hu \textit{et al.} using Pd nanocrystals in citral and cyclohexene hydrogenation.\(^15\) Yoon \textit{et al.} investigated a bi-metallic Rh–Pd/CNT (CNT = carbon nanotube) catalyst for benzene hydrogenation which displayed a much higher activity compared to Rh/CNT or Pd/CNT monometallic catalysts alone. The superior activity was attributed to a synergistic effect between Rh and Pd, but the reaction system required elevated pressure (10 bar) in order to observe sufficient activity.\(^16\)
Metal nanoparticle catalysis has progressed significantly during the last 25 years.\textsuperscript{17} However, a major drawback often reported when using nanoparticles in solution catalysis is the drop in catalytic activity and selectivity associated with particle agglomeration due to a lack of stability with time and/or reaction conditions. Accordingly, intensive research has been focused on developing approaches to increase particle stability and improve catalytic performance. In particular, numerous supports and/or stabilizers (polymers or ligands) that could limit nanoparticle evolution during their application as catalysts in solution have been studied. Among polymers employed as stabilizers of metal nanoparticles, polyvinyl pyrrolidone (PVP) efficiently controls the particle growth and contributes to obtain a uniform metal nanoparticle dispersion in the polymer matrix. For these reasons, PVP-stabilized Rh nanoparticles (RhNPs) have attracted attention for arene hydrogenation in both ionic liquids and water as reaction media at relatively low temperatures.\textsuperscript{18,19}

In this work, we report results on the mild hydrogenation of benzoic acid and its derivative benzamide to cyclohexene carboxylic acid and cyclohexane carboxamide at room temperature and atmospheric H\textsubscript{2} pressure with a RhNP/PVP nanocatalyst using water as a green and eco-friendly solvent. Furthermore, the RhNP/PVP nanocatalyst has been evaluated in aqueous phase hydrogenation of levulinic acid and its methyl ester to \( \gamma \)-valerolactone.

### Experimental part

#### Materials

All manipulations were carried out under an inert atmosphere using standard Schlenk techniques or in a glove-box if not otherwise stated. Tetrahydrofuran (THF) and \( n \)-pentane were purchased from Sigma-Aldrich, purified by column-filtration and degassed by means of three freeze–pump–thaw cycles before use. Other solvents and/or reagents were purchased from Sigma-Aldrich and used without further purification except for PVP that was dried under vacuum over P\textsubscript{2}O\textsubscript{5} at 80 °C for 3 days prior to use. The rhodium precursor \([\text{Rh}(\eta^3\text{-C}_3\text{H}_5)_3]\) was synthesized from RhCl\textsubscript{3}·3H\textsubscript{2}O (Johnson Matthey) and CH\textsubscript{3}═CHCH\textsubscript{2}MgCl (Sigma-Aldrich; solution 2.0 M in THF) following a published preparation method.\textsuperscript{20} Hydrogen gas (Alphagaz) was purchased from Air Liquide.

#### Synthesis of RhNPs/PVP

The \([\text{Rh}(\eta^3\text{-C}_3\text{H}_5)_3]\) metal precursor (150 mg, 0.663 mmol) was placed in a Fisher–Porter bottle and left under vacuum for 30 min. The Fisher–Porter bottle was then cooled to \(-80 \) °C and a THF solution (150 mL) containing 680 mg of PVP (\( M_w = 40 \ 000 \text{ g mol}^{-1} \)) was added to the rhodium complex leading to a yellow solution. The reaction mixture was then allowed to warm up to room temperature before pressurization with H\textsubscript{2} (3 bar). After 10 min, the yellow solution turned into a black colloidal solution indicating the formation of NPs. The solution was left for stirring under a H\textsubscript{2} atmosphere for an additional 16 h to ensure complete decomposition of the metal precursor. Then excess of H\textsubscript{2} was removed under vacuum and the colloidal solution was concentrated to 10 mL before addition of \( n \)-pentane in order to precipitate the RhNPs. The resulting RhNP/PVP solid was washed twice with \( n \)-pentane, filtered and dried under vacuum overnight and the crystalline dark grey powder obtained (~600 mg) was kept under an inert atmosphere until use.

#### Characterization of RhNPs/PVP

**TEM and HR-TEM analyses.** Samples for transmission electron microscopy (TEM) and high resolution HR-TEM analyses were prepared by slow evaporation of a drop of the crude colloidal solution deposited onto a holey carbon-covered copper grid under argon (in glove-box). TEM and HR-TEM analyses were performed on a JEOL JEM 1400 microscope operating at 120 kV and a JEOL JEM 2010 microscope working at 200 kV with a resolution point of 2.5 Å and equipped with an Energy-Dispersive X-ray (EDX; Noran) spectrometer, respectively. Enlarged micrographs were used for treatment with ImageJ software to obtain a statistical size distribution and the nanoparticle mean diameter. FFT treatments were carried out with Digital Micrograph Version 1.80.70 to determine the NP crystalline structure.

**ICP-AES analyses.** The Rh content of the RhNP/PVP catalyst was quantified by inductively coupled plasma atomic emission spectroscopy (ICP-AES) using a Thermo Scientific iCAP 6300 DUO spectrometer with a 3-channel, 12-roller pump and a 27.12 MHz solid state RF plasma generator. Mineralization of the RhNP/PVP sample was performed in \textit{aqua regia} solution.

**XPS analyses.** X-ray photoelectron spectroscopy (XPS) data were acquired with a ThermoScientific system at room temperature using Al-K\textsubscript{α} radiation (1484.6 eV) as the excitation X-ray source. During analysis the pressure in the chamber was maintained at 2 × 10\textsuperscript{-10} mbar. The XPS measurements were then performed in the electron binding energy range corresponding to Rh 3d excitations and C, N and O 1s excitations. All samples were measured twice and the reported values are the average of the two analyses.

#### General hydrogenation procedure

All reactions were performed in a 300 mL stainless steel high pressure autoclave equipped with an electrically heated jacket, a turbine stirrer with a variable speed magnetic driver and a liquid sampling line. In a typical reaction, the reactor was loaded with the substrate (0.5 mmol), water (50 mL) and catalyst (10 mg). Afterwards, the reactor was pressurized with H\textsubscript{2} (4 bar) three times followed by evacuation to displace residual air in the reactor. The autoclave was then filled with H\textsubscript{2} (1 or 10 bar), heated to the desired temperature and the reaction was initiated by stirring the mixture at 320 rpm. After the selected reaction time the autoclave was cooled down to room temperature. An aliquot of the reaction mixture was subsequently analyzed by gas chromatography (GC-FID) using a chromatograph (Agilent 6890N) equipped with an HP-5 capillary column (Agilent, J&W, 30 m × 320 µm). Gas chromato-
graphy coupled to mass spectrometry (GC-MS) was also performed on Agilent 6850N equipment fitted with the same capillary column.

**Results and discussion**

**Characterization of RhNPs/PVP**

Rhodium nanoparticles stabilized by the PVP polymer (RhNPs/PVP) were synthesized following the so-called “organometallic approach” previously developed by some of the authors.\textsuperscript{21,22} This method allows us to prepare well-controlled NPs that display interesting catalytic properties.\textsuperscript{23} The organometallic complex $[\text{Rh}(\eta^3-\text{C}_3\text{H}_5)_3]$ was used as the rhodium source, and decomposed in THF solution at room temperature under a $\text{H}_2$ atmosphere and mild conditions (3 bar $\text{H}_2$).\textsuperscript{24} The main advantage of this method is the formation of propane as the only by-product, which is inert towards the metallic surface and can be easily removed, thus allowing to obtain uncoordinated metal NPs in the PVP stabilizing matrix. The PVP matrix retains NPs that are both soluble in organic solvents and water.

The RhNPs/PVP were characterized by electron microscopy at low (TEM) and high resolution (HR-TEM) coupled with energy-dispersive X-ray spectroscopy (EDX) techniques to determine the dispersion of the particles inside the PVP polymer and their mean diameter as well as the crystalline structure. TEM analysis performed on the crude colloidal solution confirmed the presence of small, spherical, and very well-dispersed Rh NPs with a mean size of ca. 2.2 (±0.9) nm. The particles were found to be homogeneous in shape with a quite narrow size distribution (Fig. 2a and c). HR-TEM analysis (Fig. 2b; [011] atomic planes) revealed well-crystallized NPs with a face centered cubic (fcc) packed structure as expected for metallic Rh(0). The EDX analysis showed a clear signal for elemental Rh as well as well-identified signals for C and N atoms from the PVP polymer that embeds the particles (Fig. 2d).

The oxidation state and the surrounding chemical environment of RhNPs/PVP were examined by X-ray photoelectron spectroscopy (XPS). Fig. 3a shows XPS spectra with the signals corresponding to C, N and O from PVP used as a stabilizer and Rh (elemental survey). A signal found at about 200.5 eV (Fig. 3a, inset) is attributed to contamination of Cl from the organometallic precursor. However, it is quite insignificant since it is only about 0.13% of the corresponding intensity compared to the C 1s level signal. Fig. 3b shows the 3d core level XPS spectra for RhNPs/PVP. The lower binding energy signals at 307.8 eV (3d_{5/2}) and at about 311.9 eV (3d_{3/2}) confirm the metallic state of the Rh NPs. The higher binding energy peak at 313–315 eV (3d_{3/2}) suggests the presence of rhodium oxide species, and a comparison with earlier

![Fig. 2](image-url) (a) TEM and (b) HR-TEM images of the as-prepared RhNPs/PVP; (c) NP size distribution histogram; (d) EDX analysis spectrum.
investigations is in agreement with Rh$^{3+}$ species in Rh$_2$O$_3$. The presence of such species can be attributed to partial oxidation during sample preparation and/or sample introduction to the spectrometer. However, even if such rhodium oxide species are present, they are likely to be reduced under the hydrogenation reaction conditions to Rh(0). A small signal is further detected at 304 eV and attributed to the 3d level with different chemical environments on the surface. The Rh metal content in the RhNPs/PVP was determined by ICP-AES to be equal to 7.37 wt%.

Selective hydrogenation of arenes with RhNPs/PVP

Benzamide (3 in Fig. 4) was chosen as a first substrate for the optimization of the selective hydrogenation reaction conditions, because of its low price compared to benzoic acid. As the nature of the solvent (protic, aprotic, polar or apolar) is a well-known parameter influencing catalyst activity and selectivity in hydrogenation reactions, three different solvents were initially tested; n-hexane, methanol and water, for the benzamide hydrogenation to cyclohexane carboxamide under mild reaction conditions (80 °C, 1 bar H$_2$, 2 h reaction time). Both conversion and selectivity were determined by GC and GC-MS analyses and are reported in Table 1. Water, which has the least solubility of H$_2$, gave a full conversion of benzamide and 100% selectivity towards the formation of cyclohexane carboxamide (Table 1, entry 3), whereas n-hexane, and methanol with relatively high solubility of H$_2$, were found to be much less effective; no more than 39 and 71% conversion were achieved for n-hexane and methanol, respectively (Table 1, entries 1 and 2).

The study was then pursued with water as the reaction solvent to analyze the influence of temperature. At 40 and 25 °C (Table 1 entries 4 and 5) the Rh nanocatalyst displays the same high activity as at 80 °C, yielding full conversion of benzamide with 100% selectivity towards the desired cyclohexane carboxamide product. Furthermore, a control experiment with no catalyst was performed in order to ensure the indispensability of the catalyst for benzamide hydrogenation to cyclohexane carboxamide. As expected, no reaction product was achieved under the selected reaction conditions (Table 1, entry 6).

After choosing the preferred reaction conditions regarding solvent and temperature (water and 25 °C) the catalytic performance of the RhNP/PVP catalyst was evaluated for hydrogenation of alternative substrates. A series of eight other arene substrates containing diverse electron donating (EDG) or electron withdrawing (EWG) groups were selected (Fig. 4), and the obtained results are collected in Table 2. The RhNP/PVP catalyst showed excellent activity with all of the tested arene substrates resulting in conversions in the range of 74–100% and selectivity >97% to the desired ring hydrogenated products except for acetophenone 9 (Table 2, entries 1–9). Instead, the product selectivity of cyclohexyl methyl ketone from 9 was only 20% and 1-phenylethanol (keto group hydrogenation) was observed as the major product, thus indicating preferential reduction of the carbonyl group, instead of ring hydrogenation, for this substrate. Notably, the oxo group contained in benzamide 3 and benzoic acid 4 was not reduced under the applied reaction conditions. These observations corroborate with previously reported results with Rh NPs stabilized on carbon nanofibers (CNF) under similar reaction conditions. As shown in Table 2, no clear differences were found under the applied reaction conditions in the

**Fig. 4** Arene substrates examined for the selective hydrogenation with RhNPs/PVP.
Encouraged by the good performance of the RhNP/PVP catalyst in the selective hydrogenation of arenes, the hydrogenation of levulinic acid and methyl levulinate was further explored as a plausible route to obtain γ-valerolactone from biomass (Scheme 1). The reaction conditions were selected on the basis of our recently developed catalytic system with Au core and Pt shell NPs stabilized on graphitized carbon black (Au@Pt/G-CB).

For example, the hydrogenation of levulinic acid and methyl levulinate in water, leading to quantitative formation of the fuel additive γ-valerolactone under moderate reaction conditions in contrast to previously reported catalytic systems. Recycling tests of the RhNP/PVP catalyst are currently under investigation to validate its long-term stability.

**Conclusions**

Well-defined PVP-stabilized Rh nanoparticles of ca. 2.2 nm in size were obtained via the organometallic method, namely by hydrogenation of the organometallic complex [Rh(η5-C5H5)2] in the presence of PVP, and then evaluated as a catalyst in the hydrogenation of a series of arene substrates. The RhNP/PVP catalyst showed excellent activity and selectivity towards aromatic ring hydrogenation compared to other reported transition metal-based catalysts at room temperature and 1 bar H2, except for acetophenone where 1-phenylethanol was formed as the major product. In addition, the prepared RhNP/PVP nanomaterial was shown to be a highly promising catalyst for the hydrogenation of levulinic acid and methyl levulinate in water, leading to quantitative formation of the fuel additive γ-valerolactone under moderate reaction conditions in contrast to previously reported catalytic systems. Recycling tests of the RhNP/PVP catalyst are currently under investigation to validate its long-term stability.
