Citation (APA):
A Mouse Model of the Auditory Nerve to Study Cochlear Synaptopathy

Gerard Encina-Llamas¹, Torsten Dau¹, James M. Harte² and Bastian Epp¹

¹ Hearing Systems, Technical University of Denmark (DTU) - ² Interacoustics Research Unit (IRU)

Objective: Investigate the effects of cochlear synaptopathy on auditory nerve function.

Methods:
- **Middle-ear filter:**
  - CAT middle-ear filter - Magnitude
  - MOUSE middle-ear filter - Magnitude

- **AN tuning:**
  - AN tuning - CAT (m = 85%)
  - AN tuning - MOUSE (m = 85%)

- **AN thresholds:**
  - AN threshold - Taberner & Liberman (2005)
  - Simulated AN thresholds

Results I:
- **EFRs recorded in mice:**
  - Non-synaptrophic frequency
    - (f = 12.1 kHz)
  - Sympathetic frequency
    - (f = 0.056 kHz)

- **Simulated EFRs using the CAT model:**
  - Non-synaptrophic frequency
    - (f = 12.1 kHz)
  - Sympathetic frequency
    - (f = 0.056 kHz)

- **Simulated EFRs using the MOUSE model:**
  - Non-synaptrophic frequency
    - (f = 12.1 kHz)
  - Sympathetic frequency
    - (f = 0.056 kHz)

Conclusion:
- The modifications applied to “mousify” the AN model (ME filter fitting) and range of sensitive CFs were sufficient to generally account for the mouse AN thresholds.
- The mouse model improved significantly the simulation of EFR level-growth functions in mice with respect to the use of the cat model.
- Although the model simulations capture the general trend of the EFR level-growth functions, there are still discrepancies in particular at the lower and higher stimulus levels at the sympathetic frequency.
- Simulated EFRs using the mouse model at supra-threshold levels are dominated by the activity of high-SR fibers at off-frequency contributions, similarly to the humanized AN model (Encina-Llamas et al., under review).

Introduction
Several non-human animal studies have demonstrated a permanent loss of auditory nerve (AN) fiber synapses after noise overexposure, termed cochlear synaptopathy, without causing hair cell loss or altering normal auditory thresholds (e.g., Rujas and Liberman, 2009). Studies in humans are generally inconclusive, mainly because the status of the AN in humans represents a major challenge. In a previous study, we proposed the use of efferent responses (EF-R) as a tool to investigate synaptopathy both in mice and humans (Encina-Llamas et al., under review; Parthasarathy et al., 2017). Similar patterns of synaptic and non-synaptic losses in mice and humans were found. The use of a “humanized” version of the AN model by Zilany et al. (2009, 2014) could qualitatively account for the patterns observed in the human listeners. Nevertheless, the use of the original animal version of the AN model (based on the cat) failed to simulate EFRs in mice. It was argued that a species-specific AN model could improve the non-human animal simulations. Given that the mouse is the most used and best characterized species in connection with cochlear synaptopathy, the present study proposes a modification of the original AN model by Zilany et al. (2009, 2014) based on cat data adapted to the mouse.

Aim of the project
- Modify the AN model by Zilany et al. (2009, 2014) based on the cat to adapt it to the mouse.
- Due to the complexity of the AN model, it was intentionally decided to modify as few parameters as possible.
- Three main blocks were modified: the middle-ear filter, the cochlear tuning (Q10 values), and the range of sensitive characteristics (CFs).
- The ultimate goal was to use the model to simulate EFRs in non-synaptrophic and synaptic mice.

“Mousification” of the AN model
- **AN tuning:**
  - AN tuning - CAT (m = 85%)
  - AN tuning - MOUSE (m = 85%)

- **AN thresholds:**
  - AN threshold - Taberner & Liberman (2005)
  - Simulated AN thresholds

Results II:
- Analysis on- and off-frequencies and different fiber types:
  - **Analysis on- and off-frequencies and different fiber types:**
    - High-SR fibers
    - Low-SR fibers

Conclusion
- The modifications applied to “mousify” the AN model (ME filter fitting) and range of sensitive CFs were sufficient to generally account for the mouse AN thresholds.
- The mouse model improved significantly the simulation of EFR level-growth functions in mice with respect to the use of the cat model.
- Although the model simulations capture the general trend of the EFR level-growth functions, there are still discrepancies in particular at the lower and higher stimulus levels at the sympathetic frequency.
- Simulated EFRs using the mouse model at supra-threshold levels are dominated by the activity of high-SR fibers at off-frequency contributions, similarly to the humanized AN model (Encina-Llamas et al., under review).
