Learning objectives:

1. Explain the supercritical CO₂ impregnation as a loading technique for microcontainers
2. Evaluate if the loading process is affected by the surface area exposed to the supercritical CO₂
3. Discuss if the quantity and distribution are different when loading two different poorly water soluble drugs

Introduction: Microcontainers (MCs) are polymeric cylindrical microdevices with only one side open [1]. MCs can be filled with a polymer matrix followed by loading a drug into the polymer-filled MCs using supercritical CO₂ (scCO₂) impregnation for potential use in oral drug delivery [2].

The aim of this study was to investigate the quantity, distribution and solid state form of the poorly water soluble drugs, ketoprofen and naproxen loaded into three different sizes of polymer-filled MCs using scCO₂. The different diameters of the MCs provided different surface areas of polymer exposed to the scCO₂ during the drug loading process.

Methods: MCs were fabricated in SU-8 (Fig. 1a) using two-steps of photolithography resulting in cylinders with internal diameter of 110 μm (small), 220 μm (medium) and 440 μm (large). MCs were filled manually with polyvinylpyrrolidone (PVP) K10 powder. Polymer-filled MCs were impregnated with ketoprofen or naproxen by means of scCO₂ impregnation (Fig. 1b). Ketoprofen was loaded using 100 bar, 40°C for one hour as scCO₂ impregnation parameters, whereas for naproxen, the parameters were set at 120 bar and 45°C for one hour. The *in vitro* release of ketoprofen and naproxen from the impregnated MCs was analyzed in 10 mM PBS solution at 37°C using a μDISS profiler. For evaluation of the solid state form of the drugs in the MCs for the different sizes, Raman spectroscopy and X-Ray Powder Diffraction were used. Raman maps were acquired using a DXR Raman microscope to analyze the distribution of the drug in the MCs.

Results: The quantity of the drug loaded into the different sizes of MCs and for the two drugs was not found to be statistically different. The release of naproxen or ketoprofen from the MCs showed similar kinetics for the different sizes and for the two drugs, reaching 90 % release within the first 10 min. By the use of Raman microscopy, it was evaluated if the exposed surface area influenced the distribution of the drugs in the MCs. An example with ketoprofen can be seen in Fig. 2, where the distribution of the drug in the uppermost layers inside the MCs was evaluated. Ketoprofen loaded into the MCs was found to be in its amorphous form, whereas naproxen was in a metastable form.

Conclusions: MCs having different surface areas exposed to the scCO₂ did not affect the quantity and release kinetics of loaded ketoprofen or naproxen.
