Introduction

Repair of DNA damages by base excision is one of the main strategies used by the cell to defend against exogenous or endogenous genotoxic stress. All organisms possess a panel of DNA repair mechanisms to repair damaged DNA and to maintain viability and genomic stability. Among these DNA repair mechanisms, base excision repair (BER) is one of the most highly conserved. Enzymes of the BER pathway act to remove the abasic fragment, fill the nucleotide gap, and seal the nick. AP endonucleases from Escherichia coli are classified into two main families termed exonuclease III (ExoIII or Xth) and endonuclease IV (EndoIV or Nfo).

The ExoIII protein of E. coli is a 3'-phosphatase capable of activating DNA substrates for polymerase-mediated primer extension (Richardson and Kornberg, 1964), and has AP endonuclease, 3'-5' exonuclease and RNase H activity (Demple and Harrison, 1994; Wilson et al., 1998). The 3'-phosphodiesterase and AP endonuclease activities of ExoIII play a major role in the BER pathway. Interestingly, Neisseria meningitidis possesses two AP endonucleases that have distinct activities in DNA repair: one is a typical Neisserial AP endonuclease (NApe), whereas the other is a specialised 3'-phosphodiesterase Neisserial exonuclease (NExo) (Carpenter et al., 2007).

The human major abasic endonuclease is Ape1, an ExoIII homologue (Wilson and Barsky, 2001). Unlike ExoIII, the human enzyme has relatively poor 3'-5' exonuclease activity (Suh et al., 1997), but exhibits AP endonuclease activity (Seki et al., 1992; Wilson et al., 1995) as well as very selective 3'-phosphodiesterase activity (Suh et al., 1997). Ape1 was found to be the first prokaryotic AP nuclease that exhibits such high identity to human Ape1 nuclease. The very high expression level (57% of total soluble proteins) of fully active and soluble His6-tagged Tte AP enzyme with His6-tag on C-terminal end was obtained in Escherichia coli Rosetta (DE3) pLysS. The active enzyme was purified up to 98% homogeneity in one chromatographic step using metal-affinity chromatography on Ni2+-IDA-Sepharose resin. The yield was 90 mg (14,000 kU) of pure Tte AP from 1 liter of culture. Because of the endonuclease activity of Tte AP exonuclease, the enzyme was applied in PCR amplification of long DNA templates. Tte AP exonuclease eliminated AP-sites in DNA template and improved the efficiency of DNA amplification.

Key words: AP endonuclease, AP site, DNA damage, Polymerase Chain Reaction Thermoanaerobacter tengcongensis
major 3'-nuclease that can excise analogs of nucleotides (Chou et al., 2000). The nuclease specificity of Ape1 and Ape2 was recently investigated (Hadi et al., 2002). It was found that mutation at F226 and W280 of Ape1 increases 3'-5' exonuclease activity. Recently discovered yeast Eth1/Apn2 and human Ape2 proteins (Bennett, 1999; Hadi and Wilson, 2000; Johnson et al., 1998; Unk et al., 2000) exhibit high similarity within the core of nuclease domains of Ape1 and ExoIII, but show relatively poor AP endonuclease and 3'-repair activities (Bennett, 1999; Hadi and Wilson, 2000; Unk et al., 2000; Unk et al., 2001).

The thermophilic AP endonuclease from the archaeon *Archaeoglobus fulgidus* was described by Schmiedel et al. The enzyme shared 33% overall sequence identity and 55% similarity to ExoIII. It showed a strong Mg²⁺ dependent nicking activity at AP-sites, nicking of undamaged double-stranded (ds) DNA and a weak exonucleolytic activity (Schmiedel et al., 2009).

*Thermoaerobacter tengcongensis* isolated from Chinese hot spring, a rod-shaped, Gram-negative, anaerobic bacterium that was recently described as an extremophily residing in the core of nuclease domains of Ape1 and ExoIII, but show relatively poor AP endonuclease and 3'-repair activities (Bennett, 1999; Hadi and Wilson, 2000; Unk et al., 2000; Unk et al., 2001).

The complete genome sequence of *T. tengcongensis* clone MB4T (Bao et al., 2002) consists of a 37.6% GC-content 2,689,441 base pair (bp) circular chromosome that contains 2808 predicted coding regions, 1,481 (52.7%), 2,689,441, base pair (bp) circular chromosome that contains 2808 predicted coding regions, 1,481 (52.7%), which have functional assignments, and 1,327 (47.3%) of which are of unknown function. Genome analysis also reveals that 30 genes have their homologues in the genomes of other thermophilic eubacteria and archaea.

The results of this study demonstrates that *Tte* AP exonuclease from *Thermoaerobacter tengcongensis* exhibits high similarity to human Ape1 enzyme and exhibits 3'-nuclease activity. The *Tte* AP exonuclease can be efficiently produced in *E. coli* over-expression system and large amount of fully active protein can be purified using a single-step chromatography procedure with Ni²⁺-IDA–sepharose. We also report the application of the recombinant *Tte* AP exonuclease in PCR analysis.

**Experimental**

**Materials and Methods**

**Bacterial strains, plasmids, enzymes, and reagents.** *Thermoaerobacter tengcongensis* (DSM 15242) was purchased from Deutsche Sammlung von Mikroorganismen und Zellkulturen GmbH. *E. coli* TOP10F', pUC57, were used for cloning of gene for *Tte* AP exonuclease. The Rosetta(DE3)pLysS strain and pET-30 LIC plasmid were applied for expression of His₆-tagged *Tte* AP exonuclease. Ni²⁺-IDA–sepharose 6B was prepared as described by Porath et al. (Porath and Olin, 1985). Restriction and modification enzymes were purchased from NEB (USA) and Fermentas MBI (Lithuania). The reagents for PCR, IPTG, agarose and reagents for protein purification were purchased from Sigma (USA), oligonucleotides were purchased from MWG Biotech (Germany).

**Phylogenetic analysis of AP-sites excision enzymes.** Based on the *T. tengcongensis* genomic DNA sequence (GenBank acc. No. NC003869) of the gene encoding potential AP endonuclease (ExoIII) was found (locus TTE2226) and translated into amino acid sequence. The comparison with other known eukaryotic and prokaryotic AP-sites excision enzymes was performed using program AlignX from Vector NTI Suite 7.1 software package (Invitrogen, Inc.). The phylogenetic tree was constructed using the same program regarding to Kimura’s correction and the phylogenetic tree was built using the Neighbour Joining method (NJ) of Saitou and Nei.

**Cloning of the gene encoding Tte AP exonuclease from *T. tengcongensis*.** Genomic DNA from *Thermoaerobacter tengcongensis* was isolated using Genomic DNA Prep Kit (A&A Biotechnology, Poland). The specific primers were designed: *Tte*APE1-Nde, (5’GGG-GGGCATATGAAACTCGTGATCGTGG 3’) (containing NdeI recognition site). *Tte*APE1-XhoI-His (5’GGG-GGGCTCGAGTTTTATGAGGTCCTCTTTTAC-TATAAG 3’) (containing XhoI recognition site). The bolded parts of primer sequences are complementary to the nucleotide sequences of the gene encoding *Tte* AP exonuclease, whereas 5’ overhanging ends of primers contain recognition sites for restriction endonucleases (underlined), and are designated to facilitate cloning. The reaction solution consisted of: 50 ng of the *T. tengcongensis* genomic DNA, 2 µl (10 µM) of each primer, 5 µl (10 mM) dNTPs, 5 µl 10× PCR buffer (100 mM Tris–HCl, pH 8.9, 500 mM KCl, 25 mM MgCl₂, 1% Triton X-100), 2 U of Pwo DNA polymerase (Dabrowski and Kur, 1998) and 30 cycles were performed with a temperature profile of 30 s at 94°C, 1 min at 55°C, and 1 min at 72°C. The amplified product was analyzed by electrophoresis on a 1% agarose gels stained with ethidium bromide. Specific PCR product was obtained (approximately 802 bp, 0.1 µg) and purified using Clean-Up Kit (A&A Biotechnology, Poland). The product was then phosphorylated using T4 polynucleotide kinase and then ligated with pUC57/Smal dephosphorylated plasmid vector. The *E. coli* TOP10F’ cells were transformed with the ligation mixture and colonies were assayed for the presence of the gene encoding *Tte* AP exonuclease by PCR amplification and restriction analysis. DNA fragments encoding *Tte* AP exonuclease gene were excised using Ndel and Xhol endonucleases and cloned into pET-30 LIC expression plasmid in Ndel and Xhol sites. After *E. coli* TOP10F’ transformation, four clones were selected and sequenced. After
sequencing, one of the plasmids (pET30TteAPC) was chosen and used for His<sub>6</sub>-tagged Tte AP exonuclease expression and purification procedure.

**Purification of the Tte AP exonuclease.** Rosetta (DE3)pLysS strain transformed with pET30TteAPC plasmid was grown overnight at 37°C in 10 ml LB supplemented with 50 µg/ml chloramphenicol and 34 µg/ml kanamycin and 0.5% glucose. After 24 h, 500 ml LB containing 50 µg/ml chloramphenicol and 34 µg/ml kanamycin was inoculated and the culture was followed to an O.D. of 0.3 at 600 nm. IPTG was then added to the final concentration of 0.5 mM, and then culture was continued until cells reach the stationary phase. The cells were harvested by centrifugation and the pellet was resuspended in 10 ml of buffer A (20 mM Tris-HCl, pH 7.5, 500 mM NaCl, 5 mM imidazole, 0.1% Triton X-100). Cells were disrupted by fast freezing at −80°C, and then were homogenized for 5 min, and insoluble proteins were removed by centrifugation. The clarified supernatant was further applied directly onto a Ni<sup>2+</sup>-IDA-sepharose 6B column (10 ml of bed volume) pre-equilibrated with buffer A. The column was washed preliminary with 30 ml buffer A, and with 30 ml of buffer A containing 50 mM imidazole, and washed again with buffer A containing 80 mM. The Tte AP exonuclease was eluted using buffer A containing 0.5 M imidazole.

The purity of the eluted protein was over 98%. Pure Tte AP exonuclease was dialyzed against storage buffer AG containing 50 mM Tris-HCl pH 8.0, 500 mM KCl, 50% glycerol) with PMSF (phenylmethylsulfonyl fluoride) and stored to an O.D. of 0.3 at 600

exonuclease was evaluated at different temperatures (from 37°C up to 95°C) using 10 pmol of AP-DNA and 200 U of enzyme and incubated for 15 min in 66 mM Tris-HCl (pH 8.0) buffer containing 0.5 mM Mg<sup>2+</sup>.

**Use of Tte AP exonuclease in PCR analysis.** Different amounts of the E. coli genomic DNA (300 to 0.1 ng) were depurinated by heating in 0.01 M sodium citrate buffer pH 5.1, 0.1 NaCl at 75°C for 60 min. Depurinated DNA samples were incubated in 66 mM Tris pH 8.0, 0.5 mM MgCl<sub>2</sub> with 30 U of Tte AP exonuclease was incubated at 70°C for 30 min, then the enzyme was denatured at 90°C for 5 min. Enzyme treated DNA samples were amplified. The length of DNA target was approximately 3000 bp. The PCR was carried out with cloned Pwo DNA polymerase 2.5 U/50 µl of reaction combined with Pwo dUTPase (Dabrowski and Ahring, 2003). PCR was performed using primer Sup (5′ AGGCTTGATAGAGACAGGTCGTAATCCCA G 3′) and primer Fr3 (5′ CTGGGTATCTGCTATGC 3′) and AP: 5′CTGGGTATCTGCTATGC 3′ and AP: 5′CTGGGTATCTGCTATGC 3′). The 3′-5′ exonuclease activity of Tte AP exonuclease was assayed using a dsDNA hybrid consisting of three synthetic oligonucleotides forming nicked DNA (FluoroHyb1: Fluorescein-5′ GCGGCCGCTGGCCACGCCC 3′, Hyb 2: GCTGCTCGGTGGGCGCTGAGTGCCTGGCGGCAC 3′ and Hyb3 5′GTGCCGCGCCGAGCCTACGCGC CACCGGACGGCAGGGTGGCCAGGGCGGC 3′). The 3′-5′ exonuclease activity was also investigated using hybrid DNA combined from Hyb1 and Hyb3 oligonucleotides. The 3′-nuclease activity was analyzed using FluoroHyb1 oligonucleotide. All reactions were performed at 70°C for 30 min at 66 mM Tris-HCl (pH 8.0) buffer − 20 pmol of DNA and 100 U of Tte AP exonuclease were used. The thermostability of Tte AP exonuclease was compared with other BER enzymes using the AlignX program of Vector NTI suite 7 (Invitrogen). Multiple sequence alignment was performed and the phylogenetic tree of Tte AP exonuclease is shown in Fig. 1a. The comparison indicates that group of ExoIII proteins from Clostridiaceae including T. tengcongensis AP exonuclease shows higher identity to eukaryotic AP exonucleases (human, rat, mouse, fruit fly), than to prokaryotic ExoIII proteins. Tte AP exonuclease is similar to human APE1 in 80% whereas E. coli ExoIII is similar to human APE1 in 78%. As it was described previously (Hadi et al., 2002), the comparison shows high conservation of these enzyme sequences. The high similarity between enzymes from the BER pathways is probably the consequence of their important function in DNA damage repair. Focused on E. coli ExoIII, Tte AP exonuclease and human APE1 proteins alignment is separately presented in Fig. 1b. The high similarity of Tte AP exonuclease to human Ape1 protein is clearly shown. This similarity is within the critical limits for AP site binding or catalysis where E. coli ExoIII contains different residue (Q112, L226). The analysis of predicted secondary structure also presents higher similarity of Tte AP exonuclease to Ape1 than E. coli ExoIII to APE1 protein. Highly inhibited AP endonuclease function was found in APE1 protein after substitution of residues F226A and W280I (Hadi et al., 2002).

**Results and Discussion**

**Amino acid sequence analysis of Tte AP exonuclease.** The amino acid sequence of Tte AP exonuclease was compared with other BER enzymes using the AlignX program of Vector NTI suite 7 (Invitrogen). Multiple sequence alignment was performed and the phylogenetic tree of Tte AP exonuclease is shown in Fig. 1a. The comparison indicates that group of ExoIII proteins from Clostridiaceae including T. tengcongensis AP exonuclease shows higher identity to eukaryotic AP exonucleases (human, rat, mouse, fruit fly), than to prokaryotic ExoIII proteins. Tte AP exonuclease is similar to human APE1 in 80% whereas E. coli ExoIII is similar to human APE1 in 78%. As it was described previously (Hadi et al., 2002), the comparison shows high conservation of these enzyme sequences. The high similarity between enzymes from the BER pathways is probably the consequence of their important function in DNA damage repair. Focused on E. coli ExoIII, Tte AP exonuclease and human APE1 proteins alignment is separately presented in Fig. 1b. The high similarity of Tte AP exonuclease to human Ape1 protein is clearly shown. This similarity is within the critical limits for AP site binding or catalysis where E. coli ExoIII contains different residue (Q112, L226). The analysis of predicted secondary structure also presents higher similarity of Tte AP exonuclease to Ape1 than E. coli ExoIII to APE1 protein. Highly inhibited AP endonuclease function was found in APE1 protein after substitution of residues F226A and W280I (Hadi et al., 2002).
Fig. 1. The amino acid sequence alignment of the BER pathway enzymes. (A) Phylogenetic tree of the ExoIII family from different organisms. The calculated distance values in parenthesis is followed the molecule name displayed on the tree. (B) Alignment of the AP exonuclease domains of Ape1, Tte AP exonuclease and ExoIII. Residues conserved in two or more sequences are highlighted in black (identical) or grey (similar). Residues of Ape1 that are critical for AP site binding and catalysis are indicated by an asterisk (*). Location of secondary structure elements in Ape1, Tte AP exonuclease and ExoIII (as assessed by NN_PREDICT (Kneller et al., 1990; McClelland and Rumelhart, 1988)) are marked below the respective sequences: β-strands are represented as ‘/’, and α-helices as ‘>’.
The inhibition of *E. coli* ExoIII binding to AP site was observed when substitution W212S was carried out (Shida et al., 1999). Based on these previous observations, the presence of aromatic residue of *Tte* AP exonuclease (W202) is required for efficient recognition of AP sites by ExoIII family.

**Expression of the recombinant His₆-Tagged *Tte* AP exonuclease.** The recombinant His₆-Tte AP exonuclease was produced in *E. coli* Rosetta(DE3)pLysS harbouring pET30TteAPC plasmid. The host for protein expression contains a modified pLysS plasmid (pRARE) with rarely used tRNA genes in *E. coli* and gene encoding T7 lysozyme, which strongly represses protein expression by T7 RNA polymerase binding and inhibition. Owing to a high copy in the *E. coli* cell of this plasmid the multiplication of tRNA is possible and helps to avoid the codon bias of *E. coli* and enhance the expression of heterologous proteins (Brinkmann et al., 1989; Novy et al., 2001; Seidel et al., 1992). The selected clones were grown in LB medium supplemented with chloramphenicol, kanamycin and glucose. Glucose strongly inhibits protein expression from pET vector (Fig. 2, lane 3) in *E. coli* cells and keeps stable number of plasmid copies in the cell during the overnight growth. The induction of *Tte* AP exonuclease expression was initialized by IPTG addition at **A**ₘ₉₀ of 0.3 and culture was grown for 6 h at 37°C reaching the highest protein expression level (Fig. 2, lane 4).

**Purification of the recombinant *Tte* AP exonuclease.** The purity of enzyme was examined by SDS-PAGE (Fig. 2). Soluble His₆-tagged *Tte* AP exonuclease was expressed in the cytosol (Fig. 2, lane 5). The recombinant enzyme was eluted from the column as a single peak (~98% purity) (Fig. 2, lane 6). Another band corresponding to 32 kDa was observed in SDS–PAGE of crude extract of *E. coli* Rosetta(DE3)pLysS with pET30 TteAP cultures after IPTG induction (Fig. 2, lane 4). This band was absent in the control crude extracts of *E. coli* Rosetta(DE3)pLysS culture (Fig. 2, lane 2) and in crude extracts of *E. coli* Rosetta(DE3)pLysS containing pET30TteAPC overnight culture in the presence of glucose, which strongly suppresses basal expression of proteins from the lac promoter. (Novy and Morris, 2001). Protein concentrations were estimated by the Bradford method for protein quantification (Bradford, 1976) using BSA as a standard (see Table I). The activity of recombinant *Tte* AP exonuclease was evaluated using fluorescent labeled dsDNA with inserted AP sites (Fig. 2). The products of digestion were analyzed on agarose gel. To evaluate the activity of *Tte* AP exonuclease, control experiments were conducted with restriction enzyme *ExoIII* (Fermentas MBI, Lithuania). We obtained 45 mg of pure His₆-tagged *Tte* AP exonuclease exhibiting 153 kU/mg specific activity from 500 ml of cultured *E. coli* Rosetta(DE3)pLysS+ pET30TteAPC (Table I).

**AP endonuclease, 3’-5’ exonuclease and 3’-nuclease activities of *Tte* AP exonuclease.** The evaluation of AP endonuclease activity of *Tte* AP exonuclease was performed using a synthetic DNA hybrid with two inserted AP sites (Fig. 3, Frame A). The DNA hybrid and products of the hybrid digestion were detected by fluorescein labeling the 5’ end of the oligonucleotide. The products of digestion performed in buffers with different Mg²⁺ concentration were analyzed on high-resolution NuSieve agarose (Fig. 3B). The effect of degradation is observed by change of mobility (band shift) of 5’-fluorescein labeled ssDNA or dsDNA due to DNA nicking or exonucleolytic degradation.

The *Tte* AP endonuclease activity is observed when Mg²⁺ concentration is below 1 mM, while 3’-5’ exonuclease of the AP exonuclease activity is exhibited when Mg²⁺ concentration is 1.0 mM or higher.

*Percentage of *Tte* AP exonuclease protein after purification in relation to total soluble proteins; nd – not determined*
3’-5’ exonuclease activity of *T. thermophilus* AP exonuclease was confirmed in assay with nicked DNA hybrid used as a substrate (Fig. 4A). The nicked DNA was incubated with and without *T. thermophilus* AP exonuclease in buffers with different Mg$^{2+}$ concentration. The degradation of nicked DNA was exhibited when Mg$^{2+}$ concentration reached 1.0 mM (Fig. 4B). The 5’-3’ exonuclease activity was also detected using fluorescein 5’ labeled dsDNA with 5’ cohesive end (Fig. 5A). The 3’-5’exonuclease activity was observed when Mg$^{2+}$ concentration was over 1.0 mM (Fig. 5B). The strong signal of small DNA fragment on Figure 4b and 5b is observed because of the overloading of fluorescein labeled primer (FluoroHyb1) during hybridization. This overloading was necessary to obtain stable DNA hybridization during enzymatic reaction at high temperature. Similar influence of various Mg$^{2+}$ concentrations on exonuclease activities of *E. coli* ExoIII was also observed (Wilson et al., 1998). Therefore ExoIII is applied for many molecular biology techniques: degradation of 3’ end for unidirectional mutagenesis (Henikoff, 1984), generation of a single-stranded template for DNA sequencing (Guo and Wu, 1982), site directional mutagenesis (Vandeyar et al., 1988), and many more.

Human Ape1 enzyme exhibits characteristic 3’-nuclease activity which is necessary in 3’ mismatch repair.
(Hadi et al., 2002), whereas this activity is absent in ExoIII enzyme. For the determination of 3’-nuclease activity from \textit{T. tengcongensis} AP exonuclease, the fluorescein-labeled 15 nt oligonucleotide was used (Fig. 6A). The oligonucleotide sequence was designed and examined using Vector NTI software and DNA secondary structure formation was not observed.

The oligonucleotide was incubated with the same amount of \textit{Tte} AP exonuclease at different Mg\textsuperscript{2+} concentrations at 70°C for 30 min. The degradation of ssDNA was observed when Mg\textsuperscript{2+} concentration was over 2.0 mM (Fig. 6B). The degradation of only a few nucleotides was observed due to fluorescein shielding of the 5’ terminal binding sight of the enzyme. Function and endo- and exonuclease activities of \textit{Tte} AP exonuclease are strongly depended on Mg\textsuperscript{2+} concentration. The presence of a 3’-nuclease activity domain in prokaryotic BER pathway systems is unique. A 3’-nuclease activity is a consequence of inherent high identity of the amino acid sequence, and most likely the structure similarity to human Ape1 exonuclease.

**Thermostability of \textit{Tte} AP exonuclease.** The optimal temperature of growth of \textit{T. tengcongensis} is 70°C at pH 7.0–8.0. \textit{Tte} AP exonuclease should be very stable in these conditions because it is responsible for repairing AP sites, which are generated very frequently at high temperatures. For examination of \textit{Tte} AP exonuclease thermostability, the synthetic fluorescein-labeled hybrid DNA (50 bp), with inserted AP sites, was used (Fig. 3A). 200 U of enzyme were incubated at different temperatures with 10 pmoles of hybrid DNA for 15 min and analyzed on high-resolution NuSieve agarose gel (Fig. 7). Inactivation of the enzyme was nearly complete at 84°C and above, and it is stable up to 80°C. The activity of the enzyme was also observed at 37°C, but that could be an effect of enzyme excess used in this assay.

**Enhancing PCR amplification using \textit{Tte} AP exonuclease.** A number of modifications to the basic PCR method have been published in an attempt to increase the efficiency of amplification of long PCR products efficiency as well as the specificity of the reaction. The application of ExoIII protein of \textit{E. coli} in long PCR reaction for elimination of AP sites has also been described (Fromenty et al., 2000).

\textit{Tte} AP exonuclease was employed for elimination of AP sites generated in \textit{E. coli} genomic DNA. The enzyme indicated strong 3’-5’ exonuclease and 3’-nuclease activity at 2.5 mM Mg\textsuperscript{2+} (the Mg\textsuperscript{2+} amount usually applied in PCR reaction). Its AP endonuclease activity was exhibited at 0.5 mM Mg\textsuperscript{2+}. Therefore, to avoid degradation of template DNA and primers, genomic DNA was treated with \textit{Tte} AP exonuclease at the presence of 0.5 mM Mg\textsuperscript{2+}. Then, the enzyme was inactivated at 90°C for 5 min. PCR was performed with different amounts of genomic DNA and the products of reaction were analyzed on 1% agarose gel (Fig. 8). As previously described for ExoIII enzyme (Fromenty et al., 2000), improved PCR efficiency is observed because of elimination of AP-sites, and inhibition of DNA polymerase is not observed. The inhibition of PCR is mainly observed when high amount of genomic DNA was used (300, 100 ng) (Fig. 8, lanes 2 and 3), and at a lower level of DNA (10 ng) (Fig. 8, lane 5). The high PCR inhibition effect was observed at DNA damage levels below 3 ng

Fig. 7. Thermostability of \textit{Tte} AP exonuclease. The agarose gel electrophoresis analysis of 10 pmole of AP-DNA incubated for 15 min with 200 U of \textit{Tte} AP exonuclease at indicated temperatures.
The optimal amplification efficiency was obtained for 33 ng of genomic DNA, where the ratio of AP sites of genomic DNA to amount of used for PCR DNA polymerase permits for the efficient PCR. The application of 30 U Tte AP exonuclease eliminates AP sites before PCR (Fig. 8, lanes 1–16), but the ratio between number of AP sites and the amount of enzyme is still very high for repairing the highest concentration of genomic DNA (Fig. 8, lane 10).

The depurination effect of DNA is observed especially for samples stored for extended periods (historical samples) or stored in not optimal conditions (Fromenty et al., 2000). Tte AP exonuclease could be a useful tool in amplification of DNA from this kind of samples.

**Literature**
