Outline

• Introduction
• ITER project
• Experience from MCNP calculations on fission reactors utilized on fusion
• A simplified MCNP 40° model for CTS
• Examples of calculations on CTS
• Shutdown dose rate calculation
• Prospective
ITER Schedule

- Costs: 15 billion euro
- Start of construction 2010
- First plasma: 2020 using H as test fuel
- 2027: Q=10, 50MW in 500MW out
- Deuterium+Tritium ~ 14.1 MeV (neutrons) 3.5 MeV (alfa)
- Decommissioning 2040
- DEMO ~ 2035-2040

The phases of ITER

- Site Levelling 2008
- Start Tokamak Complex excavation 2010
- Start Tokamak Complex construction 2013
- Arrival of the first manufactured component 2014
- Complete Tokamak Assembly, Begin Commissioning 2019
- First Plasma 2020
- Start Deuterium-Tritium Operations 2027
Progress on the ITER platform

Recently F4E awarded DTU and IST to partner in the design of a Collective Thomson scattering (CTS) diagnostic for ITER, F4E-FPA-393

The CTS diagnostic utilizes probing radiation of ~60 GHz emitted into the plasma and, using a mirror, collects the scattered radiation by an array of receivers.

Having a direct and unshielded view to the plasma, the first mirror will be subject to significant radiation and among the first tasks in the CTS design, is to determine whether the mirror will need active cooling.

In order to address this question, a simplified MCNP model of the relevant equatorial port plug #12 was developed based on the full C-lite ITER MCNP model.

The first steps toward benchmarking the simplified model to the full C-lite model have almost been completed.

Based on this, we have done the first calculations of heat-loads across the mirror.
Reasons for joining ITER project

• Experience in calculation of neutron and gamma fluxes and neutron activation in fission reactors by means of the Monte Carlo code MCNP

• Local Association Euratom/Risø DTU Plasma group, need for in-house neutronics calculation capabilities for designing the Collective Thomson Scattering (CTS) diagnostics system to be installed in one of the drawers in equatorial port plug #12
Layout of ITER machine

- TF-magnet
- cryostat
- vacuum vessel
- blanket modules
- test blanket port
- plasma chamber
- divertor

Reactors Physics in the Nordic Countries, Göteborg Sweden May 11-12, 2015
Status as of December 2013

- A simplified ITER 40 degree geometry input model for MCNP-5 has been developed
- Detailed geometric description of the CTS diagnostics system
- Well suited for parametric studies
- The input model has been benchmarked against the ITER A-lite model

Total heat load on mirror for different material composition
MCNP feature allowing to stop a simulation at a given surface, and restart it later

Potential to speed up series of simulations:
  - If the overall model is complicated (like C-lite)
  - If the difference between configurations are small.

CTS mirror not in C-lite yet → test SSW/SSR on simple 40 degree model (with C-lite source discussed up till now)

Capability to couple to ROOT analysis framework - proven useful in the design of the target-moderator-reflector system at the European Spallation Source
Dose Rate Criteria (inside bio-shield)

• Where planned maintenance is required the dose-rate must be less than 100µSv/hr.
• For unplanned maintenance it must be ALARA and never more than 2mSv/hr.
• Average occupational radiation exposure must be less than 500 man.mSv/yr
• Systems must be designed with ALARA in mind
Activation of especially Cobalt (50%) and Tantalum (20%) in stainless steel structure cause significant nuclear heating which is problematic in terms of maintenance.

ITER limits: 100 μSv/h 10 days after shutdown in areas were maintenance is expected.

For the CTS this means the interspace area.
Neutron attenuation through the equatorial port plug

Figure 1: Orders of magnitude of neutron attenuation from the plasma to the Port Cell
Methods for Shutdown Dose Rate Calculation

There are several methods to calculate dose rate at ITER:

- MCNP+FISPACT, MCNP6 (ACT card), "Advanced D1S method"
- In addition to these more precise methods, experience (NAR) show that for ITER a simple scaling of fast neutron (>1MeV) flux is able to predict dose-rate with a precision satisfactory for our purposes
Shutdown dose-rate calculation

- Neutron flux at entrance wall to the port interspace: $5.94807 \times 10^{-13}$ n/cm$^2$/ (source neutron) $>1$ MeV
- Conversion factor (normalization in CLITE): $1.9718 \times 10^{19}$ =>
- Flux: $5.94807 \times 10^{-13} \times 1.9718 \times 10^{19}$ n/cm$^2$/s = $6.35 \times 10^8$ n/cm$^2$/s
- Flux to shutdown-dose-rate conversions: $1.33 \times 10^{-5}$ (micro Sv/h) / (n/cm$^2$/s)
- Shutdown dose-rate:
  $6.35 \times 10^8$ n/cm$^2$/s * $1.33 \times 10^{-5}$ (micro Sv/h) / (n/cm$^2$/s)
  = 156 micro Sv/h

Stainless steel port plug

Surface for neutron flux calculation
Conclusion

- Even without cut outs in FDW to install any version of the CTS, the limit is exceeded (consistent with observations at other diagnostics)

- => a global solution is needed, shielding must be added. For the CTS, we can study relative changes in shut-down dose-rates using the above scaling approach
Prospective

- Further benchmarking our 40 degree model against C-lite MCNP reference model
- Further neutronics analyses of the CTS system to determine whether active cooling of the CTS mirror is needed
- Calculation of the CTS system contribution to the shutdown dose rate of EPP #12
Thanks for your attention
